Finite field
Boolean polynomial
Proper triangular set
Single exponential algorithm
Stream cipher

ABSTRACT

Efficient characteristic set methods for computing zeros of polynomial equation systems in a finite field are proposed. The concept of proper triangular sets is introduced and an explicit formula for the number of zeros of a proper and monic triangular set is given. An improved zero decomposition algorithm is proposed to reduce the zero set of an equation system to the union of zero sets of monic proper triangular sets. The bitsize complexity of this algorithm is shown to be $O(l^n)$ for Boolean polynomials, where n is the number of variables and $l \geq 2$ is the number of equations. We also give a multiplication free characteristic set method for Boolean polynomials, where the sizes of the polynomials occurred during the computation do not exceed the sizes of the input polynomials and the bitsize complexity of algorithm is $O(n^d)$ for input polynomials with n variables and degree d. The algorithms are implemented in the case of Boolean polynomials and extensive experiments show that they are quite efficient for solving certain classes of Boolean equations raising from stream ciphers.

1. Introduction

Solving polynomial equations in finite fields plays a fundamental role in many important fields such as coding theory, cryptology, and analysis of computer hardware. To find efficient algorithms to solve such equations is a central issue both in mathematics and in computer science (see Problem 3 in (Smale, 1998) and Section 8 of (Coron and de Weger, 2007)). Efficient algebraic algorithms for solving equations in finite fields have been developed, such as the Gröbner basis methods (Bardet et al., 2003;

Brickenstein and Dreyer, 2007; Faugère, 1999, 2002; Faugère and Ars, 2003; Kapur and Narendran, 1985; Gerdt and Zinin, 2008; Sato and Inoue, 2005) and the XL algorithm and its improved versions (Courtois et al., 2000).

The **characteristic set (CS)** method is a tool for studying polynomial, algebraic differential, and algebraic difference equation systems (Aubry et al., 1999; Boulier et al., 1995; Bouziane et al., 2001; Chou, 1988; Chou and Gao, 1990; Dahan et al., 2005; Gallo and Mishra, 1991; Gao et al., 2009; Hubert, 2000; Kalkbrener, 1993; Kapur and Wan, 1990; Lazard, 1991; Lin and Liu, 1993; Maza, 2000; Möller, 1993; Szántó, 1999; Wang, 1993; Wu, 1986; Yang et al., 1996). The idea of the method is reducing equation systems in general form to equation systems in the form of triangular sets. With this method, solving an equation system can be reduced to solving univariate equations in cascaded form. In the case of finite fields, univariate equations can be solved with Berlekamp's algorithm (Menezes et al., 1996). The CS method can also be used to compute the dimension, the degree, and the order for an equation system, to solve the radical ideal membership problem, and to prove theorems from elementary and differential geometries (Wu, 2001).

In most existing work on CS methods, the zeros of the equations are taken in an algebraically closed field which is infinite. These methods can also be used to find zeros of the equations in finite fields. But, they do not take into the account of the special properties of the finite fields and thus are not efficient for solving equations in finite fields. In this paper, we propose efficient CS methods to solve equations in the general finite field $\mathbb{F}_q$ with q elements. More precisely, we will develop efficient CS algorithms for polynomial systems in the ring

$$\mathbb{R}_q = \mathbb{F}_q[x_1, \ldots, x_n]/(\mathbb{H})$$

where $\mathbb{H} = \{x_1^q - x_1, \ldots, x_n^q - x_n\}$. Due to the special property of $\mathbb{R}_q$, the proposed CS methods are more efficient and have better properties than the general CS method.

A triangular set may have no solutions in a finite field. For instance, $x^2 + 1 = 0$ has no solution in the finite field $\mathbb{F}_3$. To avoid this problem, we introduce the concept of proper triangular sets and prove that proper triangular sets are square-free and always have solutions. We also give an explicit formula for the number of solutions of a monic and proper triangular set. We modify the definition of regular triangular sets (Aubry et al., 1999; Bouziane et al., 2001; Yang et al., 1996) in $\mathbb{R}_q$ and give an exact upper bound for the number of solutions of a regular and proper triangular set.

We propose an improved zero decomposition algorithm which allows us to decompose the zero set of a polynomial equation system in $\mathbb{R}_q$ as the disjoint union of the zero sets of proper and monic triangular sets. As a consequence, we can give an explicit formula for the number of solutions of the equation system. We prove that our elimination procedure to compute a triangular set needs a polynomial number of polynomial multiplications, which is not valid for the general CS method.

An element in $\mathbb{R}_2$ is called a Boolean polynomial. Solving Boolean polynomial systems is especially important and more methods are available. This paper will focus on CS methods. We show that for Boolean polynomial equations, the CS method proposed in this paper and that proposed in (Chai et al., 2008) for Boolean polynomials could be further improved.

Firstly, we show that the bitsize complexity of the algorithm proposed in this paper is $O(l^n)$ for Boolean polynomials, where n is the number of variables and $l \geq 2$ is the number of equations. This is the first complexity analysis for the Ritt–Wu style zero decomposition algorithms. The results in (Gallo and Mishra, 1991) are only for the procedure to compute the CS of an ideal, which is similar to the well-ordering procedure in the Ritt–Wu style decomposition (Wu, 1986). In (Szántó, 1999), a zero decomposition algorithm based on the computation of resultants is given, whose complexity is also single exponential. It seems to us that although the algorithms proposed in (Gallo and Mishra, 1991; Szántó, 1999) have nice complexity bounds, they are practically very inefficient. On the other hand, the algorithm proposed in this paper is practically very efficient as shown by the experiments presented in Section 6.

We also present a multiplication-free CS algorithm in $\mathbb{R}_2$, where the size of the polynomials occurring in the well-ordering procedure is bounded by the size of the input polynomial system and the worst case bitsize complexity of the algorithm is roughly $O(n^d)$, where n is the number of indeterminates and d the degree of the input polynomials. This result is surprising, because repeated

additions of polynomials can also generate polynomials of exponential sizes. In the general CS method, the size of the polynomials is exponential (Gallo and Mishra, 1991; Szántó, 1999). Our result also means that for a fixed d, the well-ordering procedure is a polynomial-time algorithm in n. The bottle neck problem of intermediate expression swell is effectively avoided for certain classes of problems due to the low complexity of the well-ordering procedure and the usage of SZDD (Minto, 1993). Our experimental results also support this observation.

The algorithms are implemented in the case of Boolean polynomials. We conduct extensive experiments of our methods for three kinds of polynomial systems. These systems are generated in totally different ways, but they all have the block triangular structure. By block triangular structure, we mean that the polynomial set can be divided into disjoint sets such that each set consists of polynomials with the same leading variable and different sets have different leading variables. Polynomial sets generated in many classes of stream ciphers are in triangular block form. The experiments show that our improved algorithm is very effective for solving these polynomial equations comparing to existing methods. We do not claim that our algorithm is faster in all cases. For instance, the first HFE Challenge, which was solved by the Gröbner basis algorithm (Faugère and Joux, 2003; Patarin, 1996), cannot be solved by our algorithm.

The rest of this paper is organized as follows. In Section 2, we introduce the notations. In Section 3, we prove properties for the proper triangular sets. In Section 4, we present the improved zero decomposition algorithm. In Section 5, we present a CS algorithm in $\mathbb{R}_2$. In Section 6, we present the experimental results. In Section 7, conclusions are presented.

2. Notations and preliminary results

Let p be a prime number and $q = p^k$ for a positive integer k. $\mathbb{F}_q$ denotes the finite field with q elements. For an algebraic equation, we will consider the problem of finding its solutions in $\mathbb{F}_q$. Let $\mathbb{X} = \{x_1, \ldots, x_n\}$ be a set of indeterminates. Since we only consider solutions in $\mathbb{F}_q$, we can work in the ring

$$\mathbb{R}_q = \mathbb{F}_q[\mathbb{X}]/(\mathbb{H})$$

where

$$\mathbb{H} = \{x_1^q - x_1, x_2^q - x_2, \ldots, x_n^q - x_n\}. \tag{1}$$

When we want to emphasize the variables, we use the notation $\mathbb{R}_q[x_1, \ldots, x_n]$ instead of $\mathbb{R}_q$. It is easy to see that $\mathbb{R}_q$ is not an integral domain. For any $\alpha \in \mathbb{F}_q$, $x_i - \alpha$ is a zero divisor in $\mathbb{R}_q$. An element P in $\mathbb{R}_q$ has the following canonical representation:

$$P = \alpha_s M_s + \cdots + \alpha_0 M_0, \quad \alpha_i \in \mathbb{F}_q, \tag{2}$$

where M_i is a monomial and $\deg(M_i, x_j) \leq q - 1$ for any j. We still call an element in $\mathbb{R}_q$ a **polynomial**. In this paper, a polynomial is always in its canonical representation.

Let $\mathbb{P}$ be a set of polynomials in $\mathbb{R}_q$. We use $\mathrm{Zero}_q(\mathbb{P})$ to denote the common zeros of the polynomials in $\mathbb{P}$ in the affine space $\mathbb{F}_q^n$, that is,

$$\mathrm{Zero}_q(\mathbb{P}) = \{(a_1, \ldots, a_n), a_i \in \mathbb{F}_q, s.t., \forall P \in \mathbb{P}, P(a_1, \ldots, a_n) = 0\}.$$

In this paper, when we say a **variety** in $\mathbb{F}_q^n$, we mean $\mathrm{Zero}_q(\mathbb{P})$ for some $\mathbb{P} \subseteq \mathbb{R}_q[x_1, \ldots, x_n]$. Let D be a polynomial in $\mathbb{R}_q$. We define a **quasi variety** to be

$$\mathrm{Zero}_q(\mathbb{P}/D) = \mathrm{Zero}_q(\mathbb{P}) \setminus \mathrm{Zero}_q(D).$$

Let $\mathbb{P}$ be a set of polynomials in $\mathbb{F}_q[\mathbb{X}]$. Denote the zeros of $\mathbb{P}$ in an algebraically closed extension of $\mathbb{F}_q$ as $\mathrm{Zero}(\mathbb{P})$. We use $\overline{\mathbb{P}}$ to denote the image of $\mathbb{P}$ under the natural ring homomorphism:

$$\mathbb{F}_q[\mathbb{X}] \Rightarrow \mathbb{R}_q.$$

We will give some preliminary results about the polynomials in $\mathbb{R}_q$.

Lemma 1. *Use the notations just introduced. We have* $\mathrm{Zero}(\mathbb{P} \cup \mathbb{H}) = \mathrm{Zero}_q(\overline{\mathbb{P}})$, *where* $\mathbb{H}$ *is defined in* (1).

Proof. Let $P \in \mathbb{P}$. By the definition, we have $P = \overline{P} + \sum_i B_i(x_i^q - x_i)$, where B_i are some polynomials. Note that any zero in $\mathrm{Zero}_q(\overline{\mathbb{P}})$ is also a zero of $x_i^q - x_i$. Then the formula to be proved is a direct consequence of the above relation between P and $\overline{P}$. □

Lemma 2. *Let P be a polynomial in $\mathbb{R}_q$. We have $P^q = P$.*

Proof. Since $x_i^q = x_i$, for any monomial m in $\mathbb{R}_q$ we have $m^q = m$. Let $P = \sum_i \alpha_i m_i$ where m_i are monomials and $\alpha_i \in \mathbb{F}_q$. Then $P^q = (\sum_i \alpha_i m_i)^q = \sum_i \alpha_i^q m_i^q = \sum_i \alpha_i m_i = P$. □

Lemma 3. *Let* I *be a polynomial ideal in $\mathbb{R}_q$. Then* I *is a radical ideal.*

Proof. For any $f^s \in$ I with s an integer, there exists an integer k such that $q + k(q-1) \geq s$. Then $f^s f^{q+k(q-1)-s} = f^{q+k(q-1)} \in I$. By Lemma 2, $f^{q+k(q-1)} = f^q f^{k(q-1)} = f^{k(q-1)+1} = f^{q+(k-1)(q-1)} = \cdots = f^q = f$. Thus, we have $f \in I$, which implies that I is a radical ideal. □

Lemma 4. *Let* I *be a polynomial ideal in $\mathbb{R}_q$.*

(1) I $= (x_0 - a_0, \ldots, x_n - a_n)$ *if and only if* $(a_0, \ldots, a_n)$ *is the only solution of* I.
(2) I $= (1)$ *if and only if* I *has no solutions.*

Proof. If I $= (x_0 - a_0, \ldots, x_n - a_n)$, it is easy to see that $(a_0, \ldots, a_n)$ is the only solution of I. Conversely, let $(a_0, \ldots, a_n)$ be the only solution of I. By Lemma 1, we have $x_i - a_i = 0$ on Zero(I $\cup \mathbb{H}$) in $\mathbb{F}_q[\mathbb{X}]$, where $\mathbb{H}$ is defined in (1). By Hilbert's Nullstellensatz, there is an integer s such that $(x_i - a_i)^s$ is in the ideal generated by I$\cup\mathbb{H}$ in $\mathbb{F}_q[\mathbb{X}]$. Considering $\mathbb{R}_q$, it means that $(x_i - a_i)^s$ is in I. By Lemma 3, I is a radical ideal in $\mathbb{R}_q$. Thus, $x_i - a_i$ is in I. This prove (1). For (2), if I has no solution, we have Zero(I $\cup \mathbb{H}$) $= \emptyset$. By Hilbert's Nullstellensatz, $1 \in$ (I $\cup \mathbb{H}$). That is, $1 \in$ I. □

Lemma 5. *Let $P \in \mathbb{R}_q$. $\mathrm{Zero}_q(P) = \mathbb{F}_q^n$ iff $P \equiv 0$. $\mathrm{Zero}_q(P) = \emptyset$ iff $P^{q-1} - 1 \equiv 0$.*

Proof. If $P \equiv 0$, then $\mathrm{Zero}_q(P) = \mathbb{F}_q^n$. Conversely, we prove the result by induction on n. If $n = 1$, we consider the univariate polynomial $P(x) \in \mathbb{R}_q$. Suppose that $P(x) \neq 0$. Since $\deg(P, x) \leq q - 1$, P has at most $q - 1$ solutions in $\mathbb{F}_q$, a contradiction. Now assume that the result has been proved for $n = k$. For $n = k + 1$, we have $P(x_1, \ldots, x_n) = f_0 x_n^{q-1} + f_1 x_n^{q-2} + \cdots + f_{q-1}$, where f_i is a k-variable polynomial. By the induction hypothesis, if some f_i is not 0, there exists an element $(a_1, a_2, \ldots, a_k)$ in $\mathbb{F}_q^k$ such that $f_i(a_1, \ldots, a_k) \neq 0$. Then $P(a_1, \ldots, a_k)$ is a nonzero polynomial whose degree in x_{k+1} is less than q. Supposing a_{k+1} is not the solution of $P(a_1, \ldots, a_k)$, $(a_1, \ldots, a_{k+1})$ is not the solution of P, a contradiction. Thus, we have $f_i = 0$ for all i. It means that $P \equiv 0$, and the first result is proved.

If $\mathrm{Zero}_q(P) = \emptyset$, then $P \neq 0$ for any element in $\mathbb{F}_q^n$, which implies that $P^{q-1} - 1 = 0$ for any element in $\mathbb{F}_q^n$. Then $P^{q-1} - 1 \equiv 0$. Conversely, suppose that there is an element $\alpha \in \mathbb{F}_q^n$ such that $P(\alpha) = 0$, which is impossible since $P^{q-1}(\alpha) - 1 \neq 0$. Thus, $\mathrm{Zero}_q(P) = \emptyset$. □

As a consequence of Lemma 5, we have

Corollary 6. *Let $q = 2$ and $P \in \mathbb{R}_2 \setminus \mathbb{F}_2$. Then $\mathrm{Zero}_2(P) \neq \emptyset$.*

But when $q > 2$, the corollary is not correct. For example, considering $\mathbb{R}_3$, it is easy to see that $\mathrm{Zero}_3(x^2 + 1) = \emptyset$.

Lemma 7. *Let U, V, and D be polynomials in $\mathbb{R}_q$. We have*

$$(U^{q-1}V^{q-1} - 1) = (U^{q-1} - 1, V^{q-1} - 1). \tag{3}$$
$$(U^{q-1}V^{q-1} - U^{q-1} - V^{q-1}) = (U, V). \tag{4}$$
$$\mathrm{Zero}_q(UV) = \mathrm{Zero}_q(U) \cup \mathrm{Zero}_q(V). \tag{5}$$
$$\mathrm{Zero}_q(\emptyset/D) = \mathrm{Zero}_q(D^{q-1} - 1). \tag{6}$$
$$\mathrm{Zero}_q(\mathbb{P}) = \mathrm{Zero}_q(\mathbb{P} \cup \{U\}) \cup \mathrm{Zero}_q(\mathbb{P} \cup \{U^{q-1} - 1\}). \tag{7}$$

Proof. We have

$$\begin{aligned}(U^{q-1}V^{q-1}-1) &= (U^{q-1}V^{q-1}-1, U^{q-1}(U^{q-1}V^{q-1}-1))\\ &= (U^{q-1}V^{q-1}-1, U^{q-1}V^{q-1}-U^{q-1})\\ &= (U^{q-1}V^{q-1}-1, U^{q-1}-1) = (U^{q-1}-1, V^{q-1}-1).\end{aligned}$$

This proves (3). Eq. (4) can be proved similarly:

$$\begin{aligned}(U^{q-1}V^{q-1}-U^{q-1}-V^{q-1}) &= (U^{q-1}V^{q-1}-U^{q-1}-V^{q-1}, U(U^{q-1}V^{q-1}-U^{q-1}-V^{q-1}))\\ &= (U^{q-1}V^{q-1}-U^{q-1}-V^{q-1}, U) = (U, V).\end{aligned}$$

Since $\mathbb{F}_q$ is a field, (5) is obvious. For any element $\alpha \in \mathbb{F}_q^n$, $D(\alpha) \neq 0$ means that $D^{q-1}(\alpha) - 1 = 0$. Conversely, for any element $\alpha \in \mathbb{F}_q^n$, if $D(\alpha) = 0$, we have $D^{q-1}(\alpha) - 1 \neq 0$. This proves (6). Since $U(U^{q-1}-1) \equiv 0$, (7) is a consequence of (5). □

From (6) of Lemma 7, we can see that a quasi variety in $\mathbb{F}_q^n$ is also a variety.

3. Proper triangular sets in $\mathbb{R}_q$

In this section, we will introduce the concept of proper triangular sets for which we can give an explicit formula for its number of solutions.

3.1. Triangular sets

Let $P \in \mathbb{R}_q$. The **class** of P, denoted by $\mathrm{cls}(P)$, is the largest c such that x_c occurs in P. Then x_c is called the **leading variable** of P, denoted as $\mathrm{lvar}(P)$. If $P \in \mathbb{F}_q$, we set $\mathrm{cls}(P) = 0$. If $\mathrm{cls}(P) = c$, let us regard P as a univariate polynomial in x_c. We call $\deg(P, x_c)$ the **degree** of P, denoted as $\deg(P)$. The coefficient of P wrt x_c^d is called the **initial** of P, and is denoted by $\mathrm{init}(P)$. Then P can be represented uniquely as the following form:

$$P = Ix_c^d + U \tag{8}$$

where $I = \mathrm{init}(P)$ and U is a polynomial with $\deg(U, x_c) < d$. A polynomial P_1 has **higher ordering** than a polynomial P_2, denoted as $P_2 \prec P_1$, if $\mathrm{cls}(P_1) > \mathrm{cls}(P_2)$ or $\mathrm{cls}(P_1) = \mathrm{cls}(P_2)$ and $\deg(P_1) > \deg(P_2)$. If neither $P_1 \prec P_2$ nor $P_2 \prec P_1$, they are said to have the same ordering, denoted as $P_1 \sim P_2$. It is easy to see that $\prec$ is a partial order on the polynomials in $\mathbb{R}_q$.

A sequence of nonzero polynomials

$$\mathcal{A}: \ A_1, A_2, \ldots, A_r \tag{9}$$

is a **triangular set** if either $r = 1$ and $A_1 \neq 0$ or $0 < \mathrm{cls}(A_1) < \cdots < \mathrm{cls}(A_r)$. A **trivial** triangular set is a polynomial set consisting of a nonzero element in $\mathbb{F}_q$. For a triangular set $\mathcal{A}$, we denote $\mathbf{I}_{\mathcal{A}}$ to be the product of the initials of the polynomials in $\mathcal{A}$.

Let $\mathcal{A}': A_1', A_2', \ldots, A_{r'}'$ and $\mathcal{A}'': A_1'', A_2'', \ldots, A_{r''}''$ be two triangular sets. $\mathcal{A}'$ is said to be of **lower ordering** than $\mathcal{A}''$, denoted as $\mathcal{A}' \prec \mathcal{A}''$, if either there is some k such that $A_1' \sim A_1'', \ldots, A_{k-1}' \sim A_{k-1}''$, while $A_k' \prec A_k''$; or $r' > r''$ and $A_1' \sim A_1'', \ldots, A_{r''}' \sim A_{r''}''$. We have the following basic property for triangular sets.

Lemma 8. *A sequence of triangular sets steadily lower in ordering is finite. More precisely, let $\mathcal{A}_1 \succ \mathcal{A}_2 \succ \cdots \succ \mathcal{A}_m$ be a strictly decreasing sequence of triangular sets in $\mathbb{R}_q$. Then $m \leq q^n$.*

Proof. Let P be a polynomial in $\mathbb{R}_q$. If $\mathrm{cls}(P) = c$ and $\deg(P) = d$, P and x_c^d have the same ordering. Since we only consider the ordering of the triangular sets, we may assume that the triangular sets consist of powers of variables. In this case, two distinct triangular sets cannot have the same ordering. To form a triangular set of this kind, we can choose one polynomial M_i from $\{0, x_i, x_i^2, \ldots, x_i^{q-1}\}$ for each i, and the triangular set is $M_1, M_2, \ldots, M_n$. Note that when $M_i = 0$, we will remove it from the triangular set. Thus, there are $q^n - 1$ nontrivial triangular sets consist of powers of variables. Adding the trivial triangular set consist of 1, we have a sequence of triangular sets $\mathcal{C}_1 \succ \mathcal{C}_2 \succ \cdots \succ \mathcal{C}_{q^n}$. Let $\mathcal{A}_1 \succ \mathcal{A}_2 \succ \cdots \succ \mathcal{A}_m$ be a strictly decreasing sequence of triangular sets. If $\mathcal{A}_i$ is nontrivial, for $P \in \mathcal{A}_i$,

replace it by $\mathrm{lvar}(P)^{\deg(P)}$. If $\mathcal{A}_i$ is trivial, replace it by 1. Then we get a strictly decreasing sequence of triangular sets $\mathcal{B}_1 \succ \mathcal{B}_2 \succ \cdots \succ \mathcal{B}_m$. This sequence must be a sub-sequence of $\mathcal{C}_1 \succ \mathcal{C}_2 \succ \cdots \succ \mathcal{C}_{q^n}$. Hence, $m \leq q^n$. □

For two polynomials P and Q, we use $\mathrm{prem}(Q, P)$ to denote the pseudo-remainder of Q with respect to P. For a triangular set $\mathcal{A}$ defined in (9), the **pseudo-remainder** of Q wrt $\mathcal{A}$ is defined recursively as

$$\mathrm{prem}(Q, \mathcal{A}) = \mathrm{prem}(\mathrm{prem}(Q, A_r), A_1, \ldots, A_{r-1}) \quad \text{and} \quad \mathrm{prem}(Q, \emptyset) = Q.$$

Let $R = \mathrm{prem}(Q, \mathcal{A})$. Then we have

$$I_1^{s_1} I_2^{s_2} \cdots I_r^{s_r} Q = \sum_i Q_i A_i + R \tag{10}$$

where $I_i = \mathrm{init}(A_i)$ and Q_i are some polynomials. The above formula is called the **remainder formula**. Let $\mathbb{P}$ be a set of polynomials and $\mathcal{A}$ a triangular set. We use $\mathrm{prem}(\mathbb{P}, \mathcal{A})$ to denote the set of nonzero $\mathrm{prem}(P, \mathcal{A})$ for $P \in \mathbb{P}$.

A polynomial Q is **reduced** wrt $P \neq 0$ if $\mathrm{cls}(P) = c > 0$ and $\deg(Q, x_c) < \deg(P)$. A polynomial Q is **reduced** wrt a triangular set $\mathcal{A}$ if P is reduced wrt to all the polynomials in $\mathcal{A}$. It is clear that the pseudo-remainder of any polynomial wrt $\mathcal{A}$ is reduced wrt $\mathcal{A}$.

The **saturation ideal** of a triangular set $\mathcal{A}$ is defined as follows

$$\mathrm{sat}(\mathcal{A}) = \{P \in \mathbb{R}_q \mid JP \in (\mathcal{A})\}$$

where J is a product of certain powers of the initials of the polynomials in $\mathcal{A}$. We have

Lemma 9. *Let $\mathcal{A} = A_1, \ldots, A_r$ be a triangular set. Then* $\mathrm{sat}(\mathcal{A}) = (A_1, \ldots, A_r, \mathbf{I}_{\mathcal{A}}^{q-1} - 1)$

Proof. Denote $\mathrm{I} = (A_1, \ldots, A_r, A_0)$ and $A_0 = \mathbf{I}_{\mathcal{A}}^{q-1} - 1$. If $P \in \mathrm{sat}(\mathcal{A})$, then $\mathbf{I}_{\mathcal{A}}^{q-1} P \in \mathcal{A}$. There exist polynomials B_i such that $\mathbf{I}_{\mathcal{A}}^{q-1} P = \sum_{i=1}^r B_i A_i$. Hence, $P = \sum_{i=1}^r B_i A_i - P A_0 \in \mathrm{I}$. Conversely, let $P \in \mathrm{I}$. Then there exist polynomials C_i such that $P = \sum_{i=1}^r C_i A_i + C_0 A_0$. Multiply $\mathbf{I}_{\mathcal{A}}$ to both sides of the equation. Since $\mathbf{I}_{\mathcal{A}}(\mathbf{I}_{\mathcal{A}}^{q-1} - 1) = 0$, we have $\mathbf{I}_{\mathcal{A}} P = \sum_{i=1}^r \mathbf{I}_{\mathcal{A}} C_i A_i$. Thus, $P \in \mathrm{sat}(\mathcal{A})$. □

As shown by the following example, saturation ideals have different properties comparing with that in the usual polynomial ring.

Example 10. In $\mathbb{R}_3$, Let $\mathcal{A} = A_1, A_2, A_1 = (x_1 - 1)x_2, A_2 = (x_1 + 1)x_3$. Then $\mathrm{sat}(\mathcal{A}) = (A_1, A_2, (x_1^2 - 1)^2 - 1) = (x_2, x_3, x_1)$.

3.2. Proper triangular sets

As we mentioned before, a triangular set could have no zero. For example, $\mathrm{Zero}_3(x^2 + 1) = \emptyset$. To avoid this problem, we introduce the concept of proper triangular sets.

A triangular set $\mathcal{A} = A_1, A_2, \ldots, A_r$ is called **proper**, if the following condition holds: if $\mathrm{cls}(A_i) = c_i$ and $\deg(A_i) = d_i$, then $\mathrm{prem}(x_{c_i}^{q-d_i} A_i, \mathcal{A}) = 0$.

The following lemmas show that proper triangular sets always have solutions.

Lemma 11. *Let $P(x)$ be a univariate polynomial in $\mathbb{R}_q$, and suppose that* $\deg(P(x)) = d$. *If prem $(x^{q-d} P(x), P(x)) = 0$, then $P(x) = 0$ has d distinct solutions in $\mathbb{F}_q$.*

Proof. Since $P(x)$ is a univariate polynomial, $\mathrm{init}(P) \in \mathbb{F}_q$. If $\mathrm{prem}(x^{q-d} P(x), P(x)) = 0$ in $\mathbb{R}_q$, we have $x^{q-d} P(x) = Q(x) P(x)$, where $Q(x)$ is a polynomial and $\deg(Q(x)) < q - d$. Considering the above equation in $\mathbb{F}_q[x]$, there is a polynomial C such that $x^{q-d} P(x) + C(x^q - x) = Q(x) P(x)$ in $\mathbb{F}_q[x]$, where $x^{q-d} P(x) + C(x^q - x)$ is equal to the canonical representation of $\overline{x^{q-d} P(x)}$ in $\mathbb{R}_q$. Thus, we have $(x^{q-d} - Q(x)) P(x) = -C(x^q - x)$. Since all the elements of $\mathbb{F}_q$ are solutions of $x^q - x$, the q distinct elements of $\mathbb{F}_q$ are solutions of $(x^{q-d} - Q(x)) P(x)$. Note that $\deg(Q(x)) < q - d$. Then $\deg(x^{q-d} - Q(x)) = q - d$. Thus, $x^{q-d} - Q(x)$ has at most $q - d$ solutions in $\mathbb{F}_q$, which means that $P(x)$ has at least d distinct solutions in $\mathbb{F}_q$. However, $\deg(P(x)) = d$ implies $P(x)$ has at most d solutions in $\mathbb{F}_q$. Hence, we can conclude $P(x)$ has d distinct solutions in $\mathbb{F}_q$. □

A triangular set $\mathcal{A}$ is called **monic** if the initial of each polynomial in $\mathcal{A}$ is 1. A monic triangular set is of the following form:

$$A_1 = x_{c_1}^{d_1} + U_1, A_2 = x_{c_2}^{d_2} + U_2, \ldots, A_r = x_{c_r}^{d_r} + U_r$$

where U_i is a polynomial in $x_1, \ldots, x_{c_i}$ such that $\deg(U_i, x_{c_i}) < d_i$.

For a triangular set $\mathcal{A} : A_1, \ldots, A_r$, we call $\deg(A_1)\deg(A_2)\cdots\deg(A_r)$ the **degree** of $\mathcal{A}$, denoted as $\deg(\mathcal{A})$. Let $\mathbb{Y}$ be the set $\{x_i \in \mathbb{X} | \, x_i$ is the leading variable of some $A_j \in \mathcal{A}\}$. We use $\mathbb{U}$ to denote $\mathbb{X} \setminus \mathbb{Y}$ and call the variables in $\mathbb{U}$ **parameters** of $\mathcal{A}$. Then we call $|\mathbb{U}|$ the **dimension** of $\mathcal{A}$, denoted as $\dim(\mathcal{A})$.

The following result shows that a monic proper triangular set has nice properties by giving an explicit formula for the number of solutions. The result is useful because we will prove later that the zero set for any polynomial system can be decomposed as the union of the zero sets of monic proper triangular sets.

Theorem 12. *Let $\mathcal{A}$ be a monic triangular set. Then $\mathcal{A}$ is proper if and only if* $|\mathrm{Zero}_q(\mathcal{A})| = \deg(\mathcal{A}) \cdot q^{\dim(\mathcal{A})}$.

Proof. Assume that $\mathcal{A}$ is proper. For the parameters in $\mathbb{U}$, we can substitute them by any element of $\mathbb{F}_q$. Since $|\mathbb{U}| = \dim(\mathcal{A})$, there are $q^{\dim(\mathcal{A})}$ parametric values for $\mathbb{U}$. For a parametric value U_0 of $\mathbb{U}$ and a polynomial $P \in \mathbb{R}_q$, let P' denote $P(U_0)$. After the substitution, we obtain a new monic triangular set $\mathcal{A}' : A_1', \ldots, A_r'$, where $\mathrm{cls}(A_i') = \mathrm{cls}(A_i)$ and $\deg(A_i') = \deg(A_i)$. Let $c_i = \mathrm{cls}(A_i)$ and $d_i = \deg(A_i)$. Since $\mathcal{A}$ is a proper triangular set, we have $x_{c_1}^{q-d_1} A_1 = PA_1$. Then $x_{c_1}^{q-d_1} A_1' = P_1' A_1'$. By Lemma 11, A_1' has d_1 distinct solutions. For a solution α of A_1', consider $A_2'(\alpha)$. Since $\mathcal{A}$ is proper, we have $x_{c_2}^{q-d_2} A_2 = Q_1 A_1 + Q_2 A_2$ and hence $x_{c_2}^{q-d_2} A_2'(\alpha) = Q_1'(\alpha) A_1'(\alpha) + Q_2'(\alpha) A_2'(\alpha)$. Since $A_1'(\alpha) = 0$, we have $x_{c_2}^{q-d_2} A_2'(\alpha) = Q_2'(\alpha) A_2'(\alpha)$. By Lemma 11, $A_2'(\alpha)$ has d_2 distinct solutions. By repeating the process, we can prove that $\mathcal{A}'$ has $d_1 d_2 \cdots d_r = \deg(\mathcal{A})$ distinct solutions. Hence, $|\mathrm{Zero}_q(\mathcal{A})| = \deg(\mathcal{A}) \cdot q^{\dim(\mathcal{A})}$.

Conversely, let us assume that $\mathcal{A}$ has $N = \deg(\mathcal{A}) \cdot q^{\dim(\mathcal{A})}$ solutions. Since $\mathcal{A}$ is monic, it means for any parametric value U_0 of $\mathbb{U}$ and any point x in $\mathrm{Zero}_q(A_1(U_0), \ldots, A_{i-1}(U_0))$, $A_i(U_0, x)$ has $\deg(A_i)$ distinct solutions. Let $A_i = x_{c_i}^{d_i} + V_i$ for any i. For A_1, suppose $\mathrm{prem}(x_{c_1}^{q-d_1} A_1, \mathcal{A}) = R_1 \neq 0$. Then we have $(x_{c_1}^{q-d_1} - P_1) A_1 = R_1$, where P_1 is a polynomial. Choose a parametric value U_0 of $\mathbb{U}$ such that $R_1(U_0) \neq 0$. Then $A_1(U_0)$ has d_1 distinct solutions, this contradicts to $0 < \deg(R_1(U_0), x_{c_1}) < d_1$. Thus, $R_1 = 0$. Now we consider A_2. Suppose $\mathrm{prem}(x_{c_2}^{q-d_2} A_2, \mathcal{A}) = R_2 \neq 0$. Then we have two polynomials Q_1 and Q_2 such that $x_{c_2}^{q-d_2} A_2 = Q_1 A_1 + Q_2 A_2 + R_2$. Choose a parametric value U_1 of $\mathbb{U}$ such that $R_2(U_1) \neq 0$. Since $\deg(R_2, x_{c_1}) < d_1$, there is a solution x of $A_1(U_1)$ such that $R_2(U_1, x) \neq 0$. Then we have $(x_{c_2}^{q-d_2} - Q_1(U_1, x)) A_2(U_1, x) = R_2(U_1, x)$. $A_2(U_1, x)$ has d_2 distinct solutions which contradicts to $0 < \deg(R_2(U_1, x_{c_2})) < d_2$. Thus, $R_2 = 0$. Similarly, we have $\mathrm{prem}(x_{c_i}^{q-d_i} A_i, \mathcal{A}) = 0$. Hence, $\mathcal{A}$ is proper. □

As a consequence of Theorem 12, a monic proper triangular set is square-free.

The concept of regular chains is important because of it has several nice properties (Aubry et al., 1999; Bouziane et al., 2001; Yang et al., 1996). The usual definition of regular chains need to be modified as shown by the following example. This is due to the fact that $\mathbb{R}_q$ is a ring with zero divisors.

Example 13. In $\mathbb{R}_3$, let $A_1 = x_1 x_2, A_1 = (x_1^2 - 1) x_3$, and $\mathcal{A} = A_1, A_2$. According to the usual definition, $\mathcal{A}$ is a regular chain. $\mathcal{A}$ is also proper. But, $\mathrm{Zero}_3(\mathcal{A}/\mathbf{I}_{\mathcal{A}}) = \mathrm{Zero}_3(\mathrm{sat}(\mathcal{A})) = \emptyset$ since $\mathbf{I}_{\mathcal{A}} = x_1(x_1^2 - 1) = 0$ in $\mathbb{R}_3$.

For two polynomials $P, Q \in \mathbb{R}_q$, let $\mathrm{resl}(P, Q, x_s)$ be the resultant of P and Q wrt x_s in $\mathbb{R}_q$. Let $\mathcal{A}$ be a triangular set of form (9) such that $c_i = \mathrm{cls}(A_i)$. The resultant of P wrt $\mathcal{A}$ is defined recursively as: $\mathrm{resl}(P, \mathcal{A}) = \mathrm{resl}(\mathrm{resl}(P, A_r, x_{c_r}), A_1, \ldots, A_{r-1})$ and $\mathrm{resl}(P, \{\}) = P$.

A chain is called *regular* if

$$\prod_{i=1}^{n} \mathrm{resl}(I(A_i); A_1, \ldots, A_{i-1}) \neq 0.$$

Regular chains have the following property.

Theorem 14. *Let $\mathcal{A}$ be a regular and proper chain and $\mathbb{U}$ be the parameter set of $\mathcal{A}$. Then, there exists a parametric value U_0 of $\mathbb{U}$ such that* $|\text{Zero}_q(\mathcal{A}(U_0)/\mathbf{I}_{\mathcal{A}}(U_0))| = |\text{Zero}_q(\mathcal{A}(U_0))| = \deg(\mathcal{A})$.

Proof. Let $R_i = \text{resl}(I(A_i); A_1, \ldots, A_{i-1})$ and $R = \prod_{i=1}^{n} R_i$. Since $R \neq 0$ and R is a polynomial in $\mathbb{R}_q[\mathbb{U}]$, by Lemma 5, we can choose a parametric value U_0 of $\mathbb{U}$ such that $R(U_0) \neq 0$. Then, we have $R_i(U_0) \neq 0$. $R_1(U_0) \neq 0$ means that $I_1(U_0) \neq 0$. Similar to the proof of Theorem 12. we can show that $A_1(U_0)$ has $\deg(A_1)$ distinct solutions. $R_2(U_0) \neq 0$ implies that $\text{Zero}_q(I_2(U_0), A_1(U_0)) = \emptyset$. Thus, for a solution $x_{1,1}$ of $A_1(U_0) = 0$, $I_2(U_0, x_{1,1}) \neq 0$ and $A_2(U_0, x_{1,1})$ has $\deg(A_2)$ distinct solutions. Recursively, we have $|\text{Zero}_q(\mathcal{A}(U_0)/\mathbf{I}_{\mathcal{A}}(U_0))| = |\text{Zero}_q(\mathcal{A}(U_0))| = \deg(\mathcal{A})$. □

4. An efficient zero decomposition algorithm in $\mathbb{R}_q$

In this section, we will give an improved algorithm which can be used to decompose the zero set of a polynomial system into the union of zero sets of monic triangular sets. Due to the special property of $\mathbb{R}_q$, this algorithm has better properties and lower complexities than the general zero decomposition algorithm and the output is stronger.

First, note that the following zero decomposition theorem (Chou and Gao, 1990; Kalkbrener, 1993; Lazard, 1991; Maza, 2000; Wang, 1993; Wu, 1986) is still valid and the proof is also quite similar.

Theorem 15. *There is an algorithm which permits to determine for a given polynomial set $\mathbb{P}$ in a finite number of steps regular and proper triangular sets $\mathcal{A}_j$, $j = 1, \ldots, s$ such that*

$$\text{Zero}_q(\mathbb{P}) = \cup_{j=1}^{s} \text{Zero}_q(\mathcal{A}_j/\mathbf{I}_{\mathcal{A}_j}) = \cup_{j=1}^{s} \text{Zero}_q(\text{sat}(\mathcal{A}_j))$$

where $\text{sat}(\mathcal{A}_j)$ *is the saturation ideal of* $\mathcal{A}_j$.

In $\mathbb{R}_q$, we can give the following improved zero decomposition theorem which allows us to compute the number of solutions for a finite set of polynomials.

Theorem 16. *For a finite polynomial set $\mathbb{P}$, we can compute monic proper triangular sets $\mathcal{A}_j$, $j = 1, \ldots, s$ such that*

$$\text{Zero}_q(\mathbb{P}) = \cup_{i=1}^{s} \text{Zero}_q(\mathcal{A}_i)$$

such that $\text{Zero}_q(\mathcal{A}_i) \cap \text{Zero}_q(\mathcal{A}_j) = \emptyset$ *for* $i \neq j$. *As a consequence, we have*

$$|\text{Zero}_q(\mathbb{P})| = \sum_{i=1}^{s} \deg(\mathcal{A}_i) \cdot q^{\dim(\mathcal{A}_i)}.$$

In the rest of this section, we will prove the above theorem by giving a zero decomposition algorithm and analyze its complexity in the case of Boolean polynomials.

4.1. A top-down characteristic set algorithm

In this section, we will give a **top-down characteristic set algorithm TDCS** that allows us to compute a decomposition which has the properties mentioned in Theorem 16.

Before giving the zero decomposition algorithm, we first give an algorithm to compute a triangular set. The algorithm works from the polynomials with the largest class and hence is a top-down zero decomposition algorithm. The idea of top-down elimination is explored in (Kapur and Wan, 1990; Wang, 1993). The key idea of the algorithm is as follows. Let $Q = Ix_c^d + U$ be a polynomial with largest class and smallest degree in x_c in a polynomial set $\mathbb{Q}$. If $I = 1$, we can reduce the degrees of the polynomials in $\mathbb{Q}$ by taking $\mathbb{R} = \text{prem}(\mathbb{Q}, Q)$. Since $I = 1$, we have

$$\text{Zero}_q(\mathbb{Q}) = \text{Zero}_q(\mathbb{R} \cup \{Q\}).$$

If $I \neq 1$, by (7), we split the zero set into two parts:

$$\text{Zero}_q(\mathbb{Q}) = \text{Zero}_q(\mathbb{Q} \cup \{I^{q-1} - 1\}) \cup \text{Zero}_q(\mathbb{Q} \setminus \{Q\} \cup \{I, U\}). \tag{11}$$

In the first part, since $I \neq 0$ and $I^{q-1} - 1 = 0$, Q can be replaced by $Q_1 = x_c^d + I^{q-2}U$ and we can treat this part as in the first case. The second part is simpler than $\mathbb{Q}$ and can be treated recursively. The following **well-ordering procedure** is based on the above idea.

Algorithm 1. —TDTriSet($\mathbb{P}$)

Input: A finite set of polynomials $\mathbb{P}$.
Output: A monic triangular set $\mathcal{A}$ and a set of polynomial systems $\mathbb{P}^*$ such that $\text{Zero}_q(\mathbb{P}) = \text{Zero}_q(\mathcal{A}) \cup_{\mathbb{Q}\in\mathbb{P}^*} \text{Zero}_q(\mathbb{Q})$, $\text{Zero}_q(\mathcal{A}) \cap \text{Zero}_q(\mathbb{Q}_1) = \emptyset$, and $\text{Zero}_q(\mathbb{Q}_1) \cap \text{Zero}_q(\mathbb{Q}_2) = \emptyset$ for all $\mathbb{Q}_1, \mathbb{Q}_2 \in \mathbb{P}^*$.

1 Set $\mathcal{A} = \emptyset$ and $\mathbb{P}^* = \emptyset$.
2 While $\mathbb{P} \neq \emptyset$ do
  2.1 If some nonzero element α of $\mathbb{F}_q$ is in $\mathbb{P}$, $\text{Zero}_q(\mathbb{P}) = \emptyset$. Return $\mathcal{A} = \emptyset$ and $\mathbb{P}^*$.
  2.2 Let $\mathbb{P}_1 \subset \mathbb{P}$ be the polynomials with the highest class.
  2.3 Let $Q \in \mathbb{P}_1$ be a polynomial with lowest degree.
  2.4 Let $Q = Ix_c^d + U$ such that $\text{cls}(Q) = c$, $\deg(Q) = d$ and $\text{init}(Q) = I$.
  2.5 If $I = 1$ do
    2.5.1 Set $\mathbb{R} = \text{prem}(\mathbb{P}_1, Q)$.
    2.5.2 If the classes of polynomials in $\mathbb{R}$ are lower than c
        (this situation will always happen when $q = 2$), do
        $\mathcal{A} = \mathcal{A} \cup \{Q\}$.
        $\mathbb{P} = \mathbb{R} \cup \{\mathbb{P} \setminus \mathbb{P}_1\}$.
    2.5.3 Else, do
        $\mathbb{P} = \mathbb{R} \cup \{Q\} \cup \{\mathbb{P} \setminus \mathbb{P}_1\}$ and goto 2.1.
  2.6 Else do
    2.6.1 Set $Q_1 = x_c^d + I^{q-2}U$ and $\mathbb{P}_2 = \mathbb{P}_1 \setminus \{Q\}$.
    2.6.2 $\mathbb{P} = \text{prem}(\mathbb{P}_2, Q_1) \cup \{I^{q-1} - 1\} \cup \{\mathbb{P} \setminus \mathbb{P}_1\}$.
    2.6.3 $\mathbb{P}_1 = \{\mathbb{P} \setminus \{Q\}\} \cup \mathcal{A} \cup \{I, U\}$.
    2.6.4 $\mathbb{P}^* = \mathbb{P}^* \cup \{\mathbb{P}_1\}$.
    2.6.5 Set $\mathbb{R} = \text{prem}(\mathbb{P}_2, Q_1)$.
    2.6.6 If the classes of polynomials in $\mathbb{R}$ are lower than c, do
        $\mathcal{A} = \mathcal{A} \cup \{Q_1\}$.
    2.6.7 Else, set $\mathbb{P} = \mathbb{P} \cup \{Q_1\}$ and goto 2.1.
3 Return $\mathcal{A}$ and $\mathbb{P}^*$.

The following theorem shows that to compute a monic triangular set in $\mathbb{R}_q$, we need only a polynomial number of polynomial arithmetic operations.

Theorem 17. *Algorithm* **TDTriSet** *is correct and in the whole algorithm we need $O(n^2q^2+nlq)$ polynomial multiplications where $l = |\mathbb{P}|$. In particular, we need $O(nl)$ polynomial multiplications when $q = 2$.*

Proof. Let $\mathbb{P}_1 \subset \mathbb{P}$ be the set of polynomials with the highest class c and $Q \in \mathbb{P}_1$ a polynomial with lowest degree in x_c. Let $c = \text{cls}(Q)$, $d = \deg(Q)$ and $I = \text{init}(Q)$. If $I = 1$, then for $P \in \mathbb{P}_1$, as a consequence of remainder formula (10), $\text{Zero}_q(\{Q, P\}) = \text{Zero}_q(\{Q, \text{prem}(P, Q)\})$. Therefore, we have

$$\text{Zero}_q(\mathbb{P}) = \text{Zero}_q((\mathbb{P} \setminus \mathbb{P}_1) \cup \{Q\} \cup \{\text{prem}(P, Q) \neq 0 \mid P \in \mathbb{P}_1\}).$$

If $I \neq 1$, by (7), we can split $\text{Zero}_q(\mathbb{P})$ as the following two parts:

$$\text{Zero}_q(\mathbb{P}) = \text{Zero}_q(\mathbb{P} \cup \{I^{q-1} - 1\}) \cup \text{Zero}_q(\mathbb{P} \cup \{I\}) \tag{12}$$

$$= \text{Zero}_q((\mathbb{P} \setminus \{Q\}) \cup \{Q_1\} \cup \{I^{q-1} - 1\}) \cup \text{Zero}_q((\mathbb{P} \setminus \{Q\}) \cup \{I, U\}) \tag{13}$$

where $Q_1 = x_c + I^{q-2}U$. The first part of (13) can be treated similarly to the case of $I = 1$, and the second part of (13) will be a polynomial set in the output. This proves that if we have the output it must be correct.

Now let us prove the termination of the algorithm. After each iteration of the loop, the lowest degree of the polynomials with highest class in $\mathbb{P}$ will decrease. Then the highest class of the polynomials in $\mathbb{P}$ will be reduced and the polynomial Q will be added to $\mathcal{A}$. Hence, the loop will end and give a triangular set $\mathcal{A}$ and some polynomial sets $\mathbb{P}^*$.

Finally, we will analyze the complexity of the algorithm. Let $l = |\mathbb{P}|$. After each iteration, the lowest degree of the highest class of the polynomials in $\mathbb{P}$ will be reduced at least by one. Then, this loop will execute at most $n(q-1)$ times. After each iteration, if $I = 1$, then the new $\mathbb{P}$ has at most l polynomials. If $I \neq 1$, after this iteration there are two cases:

(a) Except Q we still have some polynomials with this class. Then, the new $\mathbb{P}$ contains at most $l + 1$ polynomials;
(b) The highest class is eliminated by Q. Then, the new $\mathbb{P}$ contains at most l polynomials.

Therefore, in the whole algorithm there are at most $n(q-2)+l$ polynomials (The number is l when $q = 2$).

In an iteration, suppose we use $Q = Ix_c^d + U$ to eliminate other polynomials. First we should set Q to be monic. It means that we should compute $Q_1 = x_c^d + I^{q-2}U$ and $I^{q-1} - 1$, so we need $2(q-2)$ polynomial multiplications. Thus, in the whole algorithm we need at most $2n(q-1)(q-2)$ polynomial multiplications in order to obtain the monic polynomials. Then we want to get $\mathrm{prem}(P, Q_1)$. Since Q_1 is monic, it takes at most one polynomial multiplication when we reduce the degree of P by one. Let D be the sum of the degrees of polynomials with highest class. Then D decreases by one after one polynomial multiplication. Therefore, we need at most $(n(q-2)+l)(q-1)-1$ multiplications to reduce D from $(n(q-2)+l)(q-1)$ to 1. At the same time, we eliminate the highest class. Thus, in the whole algorithm, we need at most $n^2(q-2)(q-1) + nl(q-1) - n$ polynomial multiplications to get the pseudo-remainders. In all, the algorithm needs $O(n^2q^2 + nlq)$ polynomial multiplications, and when $q = 2$ the number is $O(nl)$. □

Lemma 18. *Let $\mathbb{P}$ be an input of* **TDTriSet**. *Assume that there is a polynomial P in $\mathbb{P}$ such that* $\mathrm{cls}(P) = c$ *and* $\mathrm{init}(P) = 1$. *Let $\mathcal{A}$ be the monic triangular set in the output. Then, there is a polynomial $P' \in \mathcal{A}$ such that* $\mathrm{cls}(P') = c$ *and* $\deg(P') \leq \deg(P)$.

Proof. Since there is a P with class c, we need to deal with this class. And we will eliminate this class by P or by a Q with class c and lower degree. This polynomial is the P'. □

By using **TDTriSet**, we have the following **zero decomposition algorithm**.

Algorithm 2. —TDCS($\mathbb{P}$)

Input: A finite set $\mathbb{P}$ of polynomials.
Output: Monic proper triangular sets satisfying the properties in Theorem 16.

1 Set $\mathbb{P}^* = \{\mathbb{P}\}$, $\mathcal{A}^* = \emptyset$ and $\mathcal{C}^* = \emptyset$.
2 While $\mathbb{P}^* \neq \emptyset$ do
  2.1 Take a polynomial set $\mathbb{Q}$ from $\mathbb{P}^*$ and set $\mathbb{P}^* = \mathbb{P}^* \setminus \{\mathbb{Q}\}$.
  2.2 Let $\mathcal{A}$ and $\mathbb{Q}^*$ be the output of **TDTriSet** with input $\mathbb{Q}$.
  2.3 if $\mathcal{A} \neq \emptyset$, set $\mathcal{A}^* = \mathcal{A}^* \cup \{\mathcal{A}\}$.
  2.4 $\mathbb{P}^* = \mathbb{P}^* \cup \mathbb{Q}^*$.
3 Suppose $\mathcal{A}^* = \{\mathcal{A}_1, \ldots, \mathcal{A}_r\}$ and $\mathcal{A}_i = \{A_{i1}, \ldots, A_{ip_i}\}$.
4 Set $\mathbb{P}^* = \{\}$ and for i from 1 to r do
  4.1 Set $\mathcal{B} = \emptyset$.
  4.2 For j from 1 to p_i do
    4.2.1 Let $\mathrm{cls}(A_{ij}) = c_{ij}$ and $\deg(A_{ij}) = d_{ij}$.
    4.2.2 If $R = \mathrm{prem}(x_{c_{ij}}^{q-d_{ij}} A_{ij}, \mathcal{A}_i) \neq 0$, set $\mathcal{B} = \mathcal{B} \cup \{R\}$.
  4.3 If $\mathcal{B} \neq \emptyset$, set $\mathbb{P}^* = \mathbb{P}^* \cup \{\mathcal{A}_i \cup \mathcal{B}\}$.
  4.4 Else, set $\mathcal{C}^* = \mathcal{C}^* \cup \{\mathcal{A}_i\}$.
5 If $\mathbb{P}^* \neq \emptyset$, set $\mathcal{A}^* = \emptyset$ and goto 2.
6 Return $\mathcal{C}^*$.

Theorem 19. *Algorithm* **TDCS** *is correct.*

Proof. By Theorem 17, if the loop in step 2 ends, we can obtain $\mathcal{A}_1, \ldots, \mathcal{A}_q$ such that $\text{Zero}(\mathbb{P}) = \cup_i \text{Zero}(\mathcal{A}_i)$. In step 4, we check whether $\mathcal{A}_i$ is a proper triangular set. If it is proper, we save it in the output list $\mathcal{C}^*$. If $\mathcal{A}_i$ is not proper, suppose $\mathcal{A}_i = A_{i1}, \ldots, A_{ip_i}$. we add $\text{prem}(x_{c_{ij}}^{q-d_{ij}} A_{ij}, \mathcal{A}_i) \neq 0$ to $\mathcal{A}_i$, and obtain a new polynomials set $\mathcal{B}_i$. We have $\text{Zero}_q(\mathcal{A}_i) = \text{Zero}_q(\mathcal{A}_i, x_{c_{ij}}^{q-d_{ij}} A_{ij}) = \text{Zero}_q(\mathcal{A}_i, \text{prem}(x_{c_{ij}}^{q-d_{ij}} A_{ij}, \mathcal{A}_i))$. Thus, $\text{Zero}_q(\mathcal{A}_i) = \text{Zero}_q(\mathcal{B}_i)$. Then we treated $\mathcal{B}_i$ recursively by step 2. Hence, if $\{\mathcal{A}'_1, \ldots, \mathcal{A}'_s\}$ is the output of the algorithm, we have $\text{Zero}_q(\mathbb{P}) = \cup_i \text{Zero}_q(A'_i)$.

Now we prove the termination of the algorithm. Firstly, we prove the termination of step 2. For a polynomial set $\mathbb{P}$, we assign an index $(c, c_{n,q-1}, c_{n,q-2}, \ldots, c_{n,1}, \ldots, c_{1,q-1}, \ldots, c_{1,1})$ where $c_{i,j}$ is the number of polynomials in $\mathbb{P}$ and with class i and degree j and for $i > c$, $\mathbb{P}$ contains at most one polynomial with class i and this polynomial is monic. Note that, in the TDCS algorithm, we need only to do eliminations on polynomials in $\mathbb{P}$ with class smaller than or equal to c. To prove the termination of step 2, we will show that each polynomial set in $\mathbb{Q}^*$ has a smaller index than that of $\mathbb{Q}$ in the lexicographical ordering. To prove this, we need only to show that in each step of Algorithm **TDTriSet**, the updated polynomial set has a lower index than that of the original one. In Algorithm **TDTriSet**, the polynomial set $\mathbb{P}$ is updated in three ways. Firstly, a polynomial P is replaced by $\text{prem}(P, Q)$ where Q is a monic polynomial. This will decrease of leading degree of P and hence decrease the index of the polynomial set. Secondly, in step 2.6.2, the polynomial Q is replaced by Q_1 and a new polynomial $I^{q-1} - 1$ is added to the polynomial. If $\text{prem}(\mathbb{P}_2, Q_1) \neq \emptyset$, the index of $\mathbb{P}$ deceases since the degrees of certain polynomials with class c are decreased. If $\text{prem}(\mathbb{P}_2, Q_1) = \emptyset$, the index of $\mathbb{P}$ also deceases because Q_1 is now the only polynomial with class c in $\mathbb{P}$ and the first component in the index is decreased at least by one. Thirdly, in step 2.6.3, the polynomial Q is replaced by $\{I, U\}$. It is clear that the index of $\{I, U\}$ is less than the index of $\{Q\}$. It is easy to show that a strictly decreasing sequence of indexes must be finite. This proves the termination of the step 2.

Suppose we obtain $\mathcal{A}^* = \mathcal{A}_1, \ldots, \mathcal{A}_q$ after step 2. If all $\mathcal{A}_i$ are proper, the algorithm will terminate. If $\mathcal{A}_i = A_{i1}, \ldots, A_{ip_i}$ is not proper, similar as above, we obtain a polynomial set $\mathcal{B}_i$ such that there exist polynomials in $\mathcal{B}_i$, which are reduced wrt $\mathcal{A}_i$. To prove the termination of the whole algorithm, it is sufficient to show that the new monic triangular sets we obtain from $\mathcal{B}_i$ in step 2 is of lower ordering than that of $\mathcal{A}_i$. Note that $\mathcal{B}_i \setminus \mathcal{A}_i$ is the set of polynomials in $\mathcal{B}_i$ which are reduced wrt $\mathcal{A}_i$.

Now let $\mathbb{Q}_1$ be the set of polynomials with highest class in $\mathcal{B}_i \setminus \mathcal{A}_i$ and Q be the one of lowest degree in $\mathbb{Q}_1$. Let $Q = Ix_c^d + U$. Then in **TDTriSet**, we splits $\text{Zero}_q(\mathcal{B}_i)$ into two parts:

$$\text{Zero}_q(\mathcal{B}_i) = \text{Zero}_q(\{\mathcal{B}_i \setminus \{Q\}\} \cup \{x_c^d + I^{q-2}U\} \cup \{I^{q-1} - 1\}) \cup \text{Zero}_q(\{\mathcal{B}_i \setminus \{Q\}\} \cup \{I, U\}).$$

Note that $\mathcal{A}_i \subseteq \mathcal{B}_i$ and if there is a polynomial A' in $\mathcal{A}_i$ with class c then $deg(A') > deg(x_c^d + I^{q-2}U)$. Thus, by Lemma 18, we can conclude that the monic triangular sets we obtain from $\{\mathcal{B}_i \setminus \{Q\}\} \cup \{x_c^d + I^{q-2}U\} \cup \{I^{q-1} - 1\}$ is of lower ordering than $\mathcal{A}_i$. For $\{\mathcal{B}_i \setminus \{Q\}\} \cup \{I, U\}$, it can be recursively treated as $\mathcal{B}_i$. Hence, we prove the termination of the algorithm. □

We use the following simple example to illustrate how the algorithm works.

Example 20. In $\mathbb{R}_3$, let $\mathbb{P} = \{x_1x_2x_3^2 - 1\}$.

In Algorithm **TDTriSet**, we have $\text{Zero}_3(\mathbb{P}) = \text{Zero}_3(x_3^2 - x_1x_2, x_1^2x_2^2 - 1) \cup \text{Zero}_3(x_1x_2, 1)$. Obviously, $\text{Zero}_3(x_1x_2, 1) = \emptyset$. Then, $\text{Zero}_3(\mathbb{P}) = \text{Zero}_3(x_3^2 - x_1x_2, x_1^2x_2^2 - 1) = \text{Zero}_3(x_3^2 - x_1x_2, x_2^2 - 1, x_1^2 - 1) \cup \text{Zero}_3(x_1^2, 1)$. The algorithm returns $\mathcal{A} = \{x_1^2 - 1, x_2^2 - 1, x_3^2 - x_1x_2\}$ and $\emptyset$.

In Algorithm **TDCS**, we check whether $\mathcal{A}$ is proper: $\text{prem}(x_3(x_3^2 - x_1x_2), \mathcal{A}) = (1 - x_1x_2)x_3$, $\text{prem}(x_2(x_2^2 - 1), \mathcal{A}) = \text{prem}(x_1(x_1^2 - 1), \mathcal{A}) = 0$. We obtain a new $\mathbb{P}' = \{\mathcal{A}, (x_1x_2 - 1)x_3\}$ such that $\text{Zero}_3(\mathbb{P}) = \text{Zero}_3(\mathbb{P}')$.

Execute Algorithm **TDTriSet** with input $\mathbb{P}'$. Choose $(x_1x_2 - 1)x_3$ to eliminate x_3. Then $\text{Zero}_3(\mathbb{P}') = \text{Zero}_3(x_3, x_3^2 - x_1x_2, x_2^2 - 1, x_1x_2 + 1, x_1^2 - 1) \cup \text{Zero}_3(x_3^2 - x_1x_2, x_1x_2 - 1, x_2^2 - 1, x_1^2 - 1)$. For the first part, we have $\text{Zero}_3(x_3, x_3^2 - x_1x_2, x_2^2 - 1, x_1x_2 + 1, x_1^2 - 1) = \text{Zero}_3(x_3, x_1x_2, x_2^2 - 1, x_1x_2 + 1, x_1^2 - 1) = \emptyset$. For the second part, we execute Algorithm **TDTriSet** again and have $\text{Zero}_3(x_3^2 - x_1x_2, x_1x_2 - 1, x_2^2 - 1, x_1^2 - 1) = \text{Zero}_3(x_3^2 - x_1x_2, x_2 - x_1, x_2^2 - 1, x_1^2 - 1) \cup \text{Zero}_3(x_3^2 - x_1x_2, x_2^2 - 1, x_1^2 - 1, x_1, 1) = \text{Zero}_3(x_3^2 - x_1x_2, x_2 - x_1, x_1^2 - 1)$. Let $\mathcal{A}' = \{x_3^2 - x_1x_2, x_2 - x_1, x_1^2 - 1\}$. Thus, $\text{Zero}_3(\mathbb{P}) = \text{Zero}_3(\mathcal{A}')$.

Returning to Algorithm **TDCS**, it is easy to check that $\mathcal{A}'$ is proper. Then we have $\mathrm{Zero}_3(\mathbb{P}) = \mathrm{Zero}_3(x_3^2 - 1, x_2 - x_1, x_1^2 - 1)$, and $|\mathrm{Zero}_3(\mathbb{P})| = 3^0(2 \times 1 \times 2) = 4$.

4.2. Complexity analysis of **TDCS** in $\mathbb{R}_2$

As we mentioned in Section 1, a complexity analysis for the zero decomposition algorithm is never given. Although, **TDCS** is much simpler than the zero decomposition algorithm over the field of complex numbers, it is still too difficult to give a complexity analysis. However, we are able to give a worst case complexity analysis for algorithm **TDCS** in the very important case of $\mathbb{R}_2$.

In $\mathbb{R}_2$, it is easy to prove that a monic triangular set is always proper. Therefore, we do not need to check whether a triangular set is proper in Algorithm **TDCS**. Moreover, by (4), we can modify the Step 2.6.3 of **TDTriSet** as

$$\mathbb{P}_1 = \{\mathbb{P} \setminus \{Q\}\} \cup \mathcal{A} \cup \{U, I\} = \{\mathbb{P} \setminus \{Q\}\} \cup \mathcal{A} \cup \{IU + I + U\},$$

and call the new algorithm **TDTriSet**$_2$. After this modification, the number of polynomials in the new component $\mathbb{P}_1$ will not be bigger than $|\mathbb{P}|$. From the proof of Theorem 17, we know that in the whole algorithm **TDTriSet**$_2$ with input $\mathbb{P}$ the number of polynomials is also at most $|\mathbb{P}|$. Then we obtain the following algorithm:

Algorithm 3. — TDCS$_2$($\mathbb{P}$)

Input: A finite set of Boolean polynomials $\mathbb{P}$.
Output: A sequence of monic triangular sets satisfying Theorem 16.

1 Set $\mathbb{P}^* = \{\mathbb{P}\}$, $\mathcal{A}^* = \emptyset$ and $\mathcal{C}^* = \emptyset$.
2 While $\mathbb{P}^* \neq \emptyset$ do
  2.1 Choose a polynomial set $\mathbb{Q}$ from $\mathbb{P}^*$.
  2.2 Let $\mathbb{Q}$ be the input of **TDTriSet**$_2$. Let $\mathcal{A}$ and $\mathbb{Q}^*$ be the output.
  2.3 if $\mathcal{A} \neq \emptyset$, set $\mathcal{A}^* = \mathcal{A}^* \cup \{\mathcal{A}\}$.
  2.4 $\mathbb{P}^* = \mathbb{P}^* \cup \mathbb{Q}^*$.
3 Return $\mathcal{A}^*$.

Theorem 21. *The bitsize complexity of Algorithm* **TDCS**$_2$ *is* $O(l^n) = O(2^{n \log l})$, *where* l *is the number of polynomials in* $\mathbb{P}$.

Remark 22. It is interesting to note that the complexity for the exhaust search algorithm is $O(\|\mathbb{P}\| \cdot 2^n)$, where $\|\mathbb{P}\|$ is the bitsize of the polynomials in $\mathbb{P}$ as defined in Section 5.2. The complexity of the exhaust search is generally better than our algorithm. But on the other hand, our algorithm can solve nontrivial problems with $n \geq 128$ as shown in Sections 6.2 and 6.3, while it is clear that the exhaust search algorithm cannot do that. The complexity to compute a Gröbner basis of $\mathbb{P} \cup \mathbb{H}$ ($\mathbb{H}$ is defined in (1)) is known to be a polynomial in d^n where d is the degree of the polynomials in $\mathbb{P}$ (Lazard, 1983). Recently, Bardet, Faugère, Salvy gave better complexity bounds under the assumption of semi-regularity (Bardet et al., 2003). It is an interesting problem that whether there exists a deterministic algorithm to find all the solutions of a Boolean polynomial system with complexity less than $O(2^n)$.

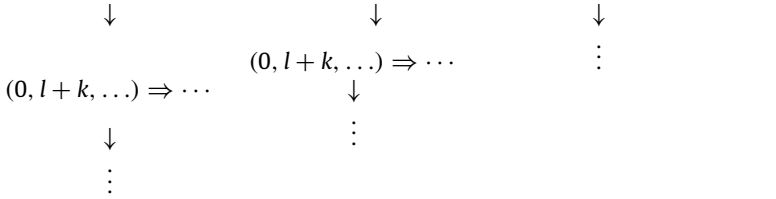
We will prove Theorem 21 in the rest of this section. In order to estimate the complexity of algorithm **TDCS**$_2$, we need to consider the worst case in the algorithm. We call the zero decomposition process in the worst case **W-Decomposition**.

In the worst case, we consider a set $\mathbb{P}$ containing l Boolean polynomials which are with the highest class n and the initials of all these l polynomials are not 1. Then we need to choose one polynomial $Q = Ix_n + U \in \mathbb{P}$ and add $I + 1$ to $\mathbb{P}$. Let $Q_1 = x_n + U$. Then we have:

$$\mathrm{Zero}_q(\mathbb{P}) = \mathrm{Zero}_q(\mathrm{prem}(\mathbb{P} \setminus \{Q\}, Q_1), \cup\{Q_1, I + 1\})) \cup \mathrm{Zero}_q(\mathbb{P} \setminus \{Q\} \cup \{IU + I + U\}). \quad (14)$$

In the worst case, we assume that the class of $I + 1$ is $n - 1$ and $\mathrm{prem}(\mathbb{P} \setminus \{Q\}, Q_1)$ contains $l - 1$ nonzero polynomials with class $n - 1$. Moreover, in the second component in (14), we have a new polynomial $IU + I + U$ which is also of class $n - 1$. When we repeat the above procedure for the two components in (14), the above situations always happen. In other words, in the worst case, when we eliminate a variable x_c, the newly generated nonzero polynomials are always of class $c - 1$.

We can illustrate the W-decomposition by the following figure:



In this figure and the rest of this section, $(l_n, l_{n-1}, \ldots, l_1)$ represents a polynomial set which contains l_i polynomials with class i. The right arrows point to the second component in (14), while the down arrows point to the first component in (14) or more precisely, to $\text{prem}(\mathbb{P} \setminus \{Q\}, Q_1) \cup \{I + 1\}$.

To solve a polynomial set $\mathbb{P}$ with l elements, we will obtain a lot of components. We can sort these components into n groups by the variables involved in them. For any $i = 1, 2, \ldots, n$, the i-th group consists of the components where the variables to be eliminated are $\{x_1, x_2, \ldots, x_i\}$. Suppose there are k_i elements in the i-th group. We define the **time-polynomial** of $\mathbb{P}$ to be

$$B(\mathbb{P}) = k_n T_n + k_{n-1} T_{n-1} + \cdots + k_1 T_1 \tag{15}$$

where T_i is a quantity to measure the complexity for executing $\mathbf{TDTriSet}_2$ whose input is a polynomial set consisting of l polynomials in i variables $\{x_1, x_2, \ldots, x_i\}$. T_i could be the bitsize of the involving polynomials or the number of arithmetic operations needed in the algorithm. Obviously, $B(\mathbb{P})$ gives the corresponding worst case complexity when the meaning of T_i is fixed.

For two polynomial sets $\mathbb{P}_1$ and $\mathbb{P}_2$, let $B(\mathbb{P}_1) = k_n T_n + \cdots + k_1 T_1$ and $B(\mathbb{P}_2) = k'_n T_n + \cdots + k'_1 T_1$. If $k_i > k'_i$ for all i, we say that $B(\mathbb{P}_1)$ is of **higher ordering** than $B(\mathbb{P}_2)$, denoted by $B(\mathbb{P}_1) > B(\mathbb{P}_2)$. We define

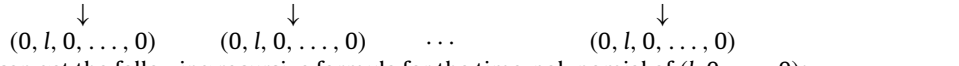
$$S(\mathbb{P}) = B(\mathbb{P}) - T_c$$

where c is the highest class of the polynomials in $\mathbb{P}$. Thus, $S(\mathbb{P})$ is the complexity for solving all the components which are originated from the second component in (14). The order of $S(\mathbb{P})$ can also be defined as $B(\mathbb{P})$. Therefore, we can use Eq. (15) as the recursive formula to compute the worst case complexity of the algorithm.

The following result shows that the problems solved with w-decomposition is indeed the worst case in terms of complexity.

Lemma 23. *Let $\mathbb{Q}$ be a polynomial set of the form $(l, 0, \ldots, 0)$, which need to be solved with w-decomposition. Let $B(\mathbb{P})$ be the time-polynomial of any other problem with $|\mathbb{P}| \leq l$. We have $B(\mathbb{Q}) \geq B(\mathbb{P})$ and $S(\mathbb{Q}) \geq S(\mathbb{P})$.*

Proof. We prove the lemma by induction. If $n = 1$, no components are generated, so we have $B(\mathbb{P}) = T_1$ and $S(\mathbb{P}) = 0$ for any problem, and the lemma holds for $n = 1$. Now suppose we have proved the lemma for $n = k$. If $n = k + 1$, we have the following figure for the w-decomposition of problem $(l, 0, \ldots, 0)$:



We can get the following recursive formula for the time-polynomial of $(l, 0, \ldots, 0)$:

$$B(l, 0, \ldots) = lT_n + B(0, l, 0, \ldots) + lS(0, l, 0, \ldots, 0) \tag{16}$$

where $(0, l, 0, \ldots)$ represents a w-decomposition problem with l input polynomials in variable $\{x_1, \ldots, x_{n-1}\}$.

For any other polynomial set $\mathbb{P}$ with no more than l input polynomials, we can write it as $(l_n, l_{n-1}, \ldots, l_1)$. If $l_n = 0$ the lemma can be proved easily from Eq. (16). Now we assume $l_n > 0$. For the l_n polynomials with class n, if there is a polynomial with initial 1, we will not generate any component when we eliminate class n, then $B(\mathbb{P}) = T_n + S(\mathbb{P}')$. Note that $|\mathbb{P}'| \leq l$ and the elements

of $\mathbb{P}'$ are all have $n-1$ variables $\{x_1, \ldots, x_{n-1}\}$. Thus $B(l, 0, \ldots) \geq B(\mathbb{P})$ and $S(l, 0, \ldots) \geq S(\mathbb{P})$ by the hypothesis.

If there exist no polynomials with initial 1 in these l_n polynomials. we have the following decomposition figure:

$$\begin{array}{ccccccc} (l_n, \ldots) \Rightarrow & (l_n - 1, \ldots) \Rightarrow & \cdots & \Rightarrow & (1, \ldots) \Rightarrow & \mathbb{P}_0 \\ \downarrow & \downarrow & & & \downarrow & \\ \mathbb{P}_1 & \mathbb{P}_2 & \cdots & & \mathbb{P}_{l_n} & \end{array}$$

Thus, we have

$$B(\mathbb{P}) = l_n T_n + B(\mathbb{P}_0) + \sum_{i=1}^{l_n} S(\mathbb{P}_i).$$

Note that $\mathbb{P}_i$ has at most $n-1$ variables $\{x_1, \ldots, x_n\}$ and $|\mathbb{P}_i| \leq l$, for any $i = 0, 1, \ldots, l_n$. By the hypothesis we have $S(\mathbb{P}_i) \leq S(0, l, 0, \ldots, 0)$ and $B(\mathbb{P}_0) \leq B(0, l, 0, \ldots, 0)$. Since $l \geq l_n$ we can conclude that $B(l, 0, \ldots) \geq B(\mathbb{P})$ and $S(l, 0, \ldots) \geq S(\mathbb{P})$. Consequently, the lemma holds in any case for $n = k + 1$. □

Proof of Theorem 21. From Eq. (16), we can obtain the value of $B(l, 0, \ldots, 0)$. Write $B(0, \ldots, 0, l, 0, \ldots, 0)$ as B_i and $S(0, \ldots, 0, l, 0, \ldots, 0)$ as S_i, where l is in the i-th coordinate. Then we have $B_n = l(T_n - T_{n-1}) + (l+1)B_{n-1}$. It is easy to check that for $n \geq 3$ we have

$$B_n = lT_n + l^2 T_{n-1} + l^2(l+1)T_{n-2} + \cdots + l^2(l+1)^{n-3}T_2 + (l+1)^{n-2}T_1.$$

If the variables of input polynomials are $\{x_1, \ldots, x_k\}$, the number of monomials occurring in $\mathbf{TDTriSet}_2$ are at most 2^k, and therefore the bitsize complexity of multiplication is $2 \cdot 4^k$. By Theorem 17, we can substitute T_k with $(2 \cdot 4^k)k(l-1)$ for any $k \geq 2$ and T_1 can be set to 0. We have $B_n \approx 2(4^3 l^{n+1} - 4^{n+1} l^3)/(l-4)^2 + 4^3 l(l^n - 2nl4^{n-2})/(l-4)$. Since $l >> 4$, we have proved Theorem 21. □

5. A multiplication free zero decomposition algorithm in R_2

It is known that a major difficulty in computing a zero decomposition is the occurrence of large polynomials which are caused mainly by multiplication of polynomials. Due to this reason, even the procedure to compute one triangular set, called well-ordering procedure in (Wu, 1986), has exponential complexity for all known CS methods. In order to overcome this difficulty, we introduce a zero decomposition algorithm in $\mathbb{R}_2$, where only additions of polynomials are used. We show that the well-ordering procedure in our multiplication free algorithm has polynomial time complexity for input polynomials with fixed degree.

5.1. The algorithm

The key idea of the algorithm is to avoid polynomial multiplications. Before doing the pseudo-remainders, we reduce the initials of the polynomials in $\mathbb{P}_1$ in step 2.2 of the Algorithm **TDTriSet** to 1 by repeatedly using (11). For such polynomials, we have the following result.

Lemma 24. *Let $P = x_c + U_1$ and $Q = x_c + U_2$ be polynomials with class c and initial 1. Then, we have* $\deg(\mathrm{prem}(Q, P)) \leq \max\{\deg(U_1), \deg(U_2)\}$.

Proof. In that case, the pseudo-remainder needs additions only: $\mathrm{prem}(Q, P) = U_1 + U_2$. The lemma follows from this formula directly. □

Based on the above idea, Algorithm **TDTriSet** can be modified to the following multiplication free (MF) well-ordering procedure to compute a triangular set.

Algorithm 4. — MFTriSet($\mathbb{P}$)
Input: A finite set of polynomials $\mathbb{P}$.
Output: A monic triangular set $\mathcal{A}$ and a set of polynomial systems $\mathbb{P}^*$ such that $\mathrm{Zero}_2(\mathbb{P}) = \mathrm{Zero}_2(\mathcal{A}) \cup_{\mathbb{Q} \in \mathbb{P}^*} \mathrm{Zero}_2(\mathbb{Q})$, $\mathrm{Zero}_2(\mathcal{A}) \cap \mathrm{Zero}_2(\mathbb{Q}_1) = \emptyset$, and $\mathrm{Zero}_2(\mathbb{Q}_1) \cap \mathrm{Zero}_2(\mathbb{Q}_2) = \emptyset$ for all $\mathbb{Q}_1, \mathbb{Q}_2 \in \mathbb{P}^*$.

1 Set $\mathbb{P}^* = \{\}$, $\mathcal{A} = \emptyset$.

2 While $\mathbb{P} \neq \emptyset$ do
  2.1 If $1 \in \mathbb{P}$, $\text{Zero}_2(\mathbb{P}) = \emptyset$. Set $\mathcal{A} = \emptyset$ and return $\mathcal{A}$ and $\mathbb{P}^*$.
  2.2 Let $\mathbb{P}_1 \subset \mathbb{P}$ be the polynomials with the highest class.
  2.3 Let $\mathbb{P}_2 = \emptyset$, $\mathbb{Q}_1 = \mathbb{P} \setminus \mathbb{P}_1$.
  2.4 While $\mathbb{P}_1 \neq \emptyset$ do
    Let $P = Ix_c + U \in \mathbb{P}_1$, $\mathbb{P}_1 = \mathbb{P}_1 \setminus \{P\}$.
    $\mathbb{Q}_2 = \mathbb{P}_1 \cup \mathcal{A} \cup \mathbb{Q}_1 \cup \mathbb{P}_2 \cup \{I, U\}$.
    $\mathbb{P}^* = \mathbb{P}^* \cup \{\mathbb{Q}_2\}$.
    $\mathbb{P}_2 = \mathbb{P}_2 \cup \{x_c + U\}$, $\mathbb{Q}_1 = \mathbb{Q}_1 \cup \{I + 1\}$.
  2.5 Let $Q = x_c + U$ be a polynomial with lowest degree in $\mathbb{P}_2$.
  2.6 $\mathcal{A} = \mathcal{A} \cup \{Q\}$.
  2.7 $\mathbb{P} = \mathbb{Q}_1 \cup \text{prem}(\mathbb{P}_2, Q)$.
3 Return $\mathcal{A}$ and $\mathbb{P}^*$.

In Step 2.4, we use formula (11) in $\mathbb{R}_2$, that is, for $P = Ix_c + U$,

$$\text{Zero}_2(P) = \text{Zero}_2(\{x_c + U, I + 1\}) \cup \text{Zero}_2(\{I, U\})$$

to split the polynomial set.

With Algorithm **MFTriSet**, we can easily give a multiplication-free zero decomposition algorithm: we just need to replace Algorithm $\mathbf{TDTriSet}_2$ by Algorithm **MFTriSet** in Algorithm $\mathbf{TDCS}_2$. We call this algorithm **MFCS**.

Algorithm 5. — MFCS($\mathbb{P}$)

Input: A finite set of polynomials $\mathbb{P}$.
Output: Monic proper triangular sets satisfying the properties in Theorem 16.

1 Set $\mathbb{P}^* = \{\mathbb{P}\}$, $\mathcal{A}^* = \emptyset$ and $\mathcal{C}^* = \emptyset$.
2 While $\mathbb{P}^* \neq \emptyset$ do
  2.1 Choose a polynomial set $\mathbb{Q}$ from $\mathbb{P}^*$.
  2.2 Let $\mathbb{Q}$ be the input of **MFTriSet**. Let $\mathcal{A}$ and $\mathbb{Q}^*$ be the output.
  2.3 if $\mathcal{A} \neq \emptyset$, set $\mathcal{A}^* = \mathcal{A}^* \cup \{\mathcal{A}\}$.
  2.4 $\mathbb{P}^* = \mathbb{P}^* \cup \mathbb{Q}^*$.
3 Return $\mathcal{A}^*$.

Remark 25. In the following, we will analyze the complexity of Algorithm **MFTriSet**. Basically, we will show that the size of the polynomials in bounded by the size of the input polynomials and the worst case complexity of this algorithm is roughly $O(n^d)$. The second result implies that for a fixed d, say $d = 2$, Algorithm **MFTriSet** is a polynomial time algorithm. Note that solving quadratic Boolean equations is NP complete. In Algorithm **MFCS**, the number branches could be exponential. We will discuss how to control the number of branches in Section 6.

5.2. Bitsize bounds of the polynomials in **MFTriSet**

In order to estimate the size of the polynomials, we introduce a **bitsize measure** for a polynomial in $\mathbb{R}_2$. Let $M = x_{i_1}x_{i_2}\cdots x_{i_k}$ be a monomial. The length of M, denoted by $\|M\|$, is defined to be k. Specially, the length of 1 is defined as 1. For a polynomial $P = M_1 + \cdots + M_t$ where M_i are monomials, $\|P\| = \sum_{i=1}^{t} \|M_i\|$ is called the **length** of P.

We first note that since Algorithm **MFCS** is multiplication free, the degrees of the polynomials occurring in the algorithm will be bounded by $d = \max_{P\in\mathbb{P}}\{\deg(P)\}$. As a consequence, the size of the polynomials occurring in the algorithm will be bounded by $O(n^d)$. Then, the size of the polynomials is effectively controlled if d is small. For all the examples in Section 6, we have $d \leq 4$ and n ranges from 40 to 128. For such examples, the polynomials have size $O(n^4)$, while the largest possible polynomial in n variables has size $O(2^n)$.

In the following theorem, we will further show that the size of the polynomials in Algorithm **MFTriSet** are effectively controlled in all cases.

Theorem 26. *Let n be the number of variables and $\mathbb{P}$ the input of Algorithm* **MFTriSet**. *Then for any polynomial T occurring in Algorithm* **MFTriSet**, *we have $\|T\| \leq \sum_{P\in\mathbb{P}} \|P\|$. If $|\mathbb{P}| > n$, then there exist n polynomials $P_1, \ldots, P_n$ in $\mathbb{P}$ such that $\|T\| \leq \|P_1\| + \|P_2\| + \cdots + \|P_n\|$.*

This result is nontrivial, because repeated additions of polynomials can increase the size of the polynomials by an exponential factor. The proof of this result is quite complicated. Intuitively, we want to show that a polynomial P used in early steps of the algorithm will be "canceled" in later steps by addition of two polynomials both containing P, that is, $(P_1 + P) + (P_2 + P) = P_1 + P_2$.

In order to prove Theorem 26, we need to prove several lemmas first. Let k be an integer and P be a polynomial. Write $P = Ix_k + U$ as a univariate polynomial in x_k. We define two operators $\mathcal{R}_k$ and $\mathcal{J}_k$ as follows:

$$\mathcal{R}_k(P) = U, \qquad \mathcal{J}_k(P) = I + 1 \quad \text{if } \mathrm{cls}(P) = k. \quad \mathcal{R}_k(P) = P, \qquad \mathcal{J}_k(P) = 0 \quad \text{if } \mathrm{cls}(P) < k. \tag{17}$$

Then, we have the following lemma

Lemma 27. *Let P and Q be polynomials with $\mathrm{cls}(P) \leq k$ and $\mathrm{cls}(Q) \leq k$. Then*

(1) $\mathcal{R}_k(P + Q) = \mathcal{R}_k(P) + \mathcal{R}_k(Q)$;
(2) $\mathcal{R}_k(P + 1) = \mathcal{R}_k(P) + 1$;
(3) *If* $\mathrm{cls}(P) = \mathrm{cls}(Q) = k$ *then* $\mathcal{J}_k(P+Q) = \mathcal{J}_k(P)+\mathcal{J}_k(Q)+1$; *otherwise* $\mathcal{J}_k(P+Q) = \mathcal{J}_k(P)+\mathcal{J}_k(Q)$.

Proof. It is easy to check. □

We can define the composition of $\mathcal{R}$ and $\mathcal{J}$ naturally. Let $\mathcal{S}_{j,k} = \{\mathcal{O}_j\mathcal{O}_{j+1}\ldots\mathcal{O}_k |\ \mathcal{O}_i = \mathcal{R}_i \text{ or } \mathcal{J}_i,\ i = j, \ldots, k\}$, where $1 \leq j \leq k \leq n$.

Lemma 28. *Let P be a polynomial with $\mathrm{cls}(P) = k$. Then $\sum_{L_{j,i}\in\mathcal{S}_{j,k}} \|L_{j,i}P\| \leq \|P\|$ for any fixed $j = 1, 2, \ldots, k$.*

Proof. For a polynomial $Q = Ix_c + U$ with $I \neq 1$, we have $\|Q\| \geq \|I\| + |U\| + 1$. $\mathcal{J}_cQ = I + 1$ and $\mathcal{R}_cQ = U$. Therefore, $\|\mathcal{J}_cQ\| + \|\mathcal{R}_cQ\| = \|I + 1\| + \|U\| \leq \|I\| + \|U\| + 1 \leq \|Q\|$. If $I = 1$, we have $\|\mathcal{J}_cQ\| + \|\mathcal{R}_cQ\| = 0 + \|U\| < \|Q\|$. For $i > c$, we have $\mathcal{J}_iQ = 0$ and $\mathcal{R}_iQ = Q$. Then $\|\mathcal{J}_iQ\| + \|\mathcal{R}_iQ\| = \|Q\|$. Hence, in any case, we have $|\mathcal{J}_iQ\| + \|\mathcal{R}_iQ\| \leq \|Q\|$.

For any j, we have $\sum_{L_{j,i}\in\mathcal{S}_{j,k}} \|L_{j,i}P\| = \sum_{L_{j+1,i}\in\mathcal{S}_{j+1,k}} (\|\mathcal{J}_jL_{j+1,i}P\|+\|\mathcal{R}_jL_{j+1,i}P\|) \leq \sum_{L_{j+1,i}\in\mathcal{S}_{j+1,k}} \|L_{j+1,i}P\| \leq \cdots \leq \|\mathcal{J}_kP\| + \|\mathcal{R}_kP\| \leq \|P\|$. □

Proof of Theorem 26. For any $k = 1, \ldots, n$, we assume that in the k-th round of **MFTriSet** we deal with the polynomials of class k. In algorithm **MFTriSet**, when we compute the pseudo-remainder of two polynomials P and Q in the k-th round, we set their initials to 1 at first, and then compute a new polynomial $\mathcal{R}_kP + \mathcal{R}_kQ$. Thus, a polynomial $P^{(k)}$ in k-th round can be obtained in three ways:

(1) $P^{(k)}$ is an input polynomial;
(2) $P^{(k)} = \mathrm{init}(Q^{(k+i)}) + 1$ for some $Q^{(k+i)}$ of round $k + i$. It means that $P^{(k)} = \mathcal{R}_{k+1}\cdots\mathcal{R}_{k+i-1}\mathcal{J}_{k+i}Q^{(k+i)}$.
(3) $P^{(k)} = \mathcal{R}_{k+j}(Q_1^{(k+j)} + Q_2^{(k+j)}) = \mathcal{R}_{k+1}\cdots\mathcal{R}_{k+j}(Q_1^{(k+j)} + Q_2^{(k+j)})$
$= \mathcal{R}_{k+1}\cdots\mathcal{R}_{k+j}Q_1^{(k+j)} + \mathcal{R}_{k+1}\cdots\mathcal{R}_{k+j}Q_2^{(k+j)}$,
where $Q_1^{(k+j)}$ and $Q_2^{(k+j)}$ are polynomials of round $k + j$.

In the cases 2 and 3, if i and j are bigger than 1, we still regard $\mathcal{R}_{k+2}\cdots\mathcal{R}_{k+i-1}\mathcal{J}_{k+i}Q^{(k+i)}$, $\mathcal{R}_{k+2}\cdots\mathcal{R}_{k+j}Q_1^{(k+j)}$ and $\mathcal{R}_{k+2}\cdots\mathcal{R}_{k+j}Q_2^{(k+j)}$ as polynomials of round $k + 1$. In this way, we can represent $P^{(k)}$ by operators and polynomials of round $k+1$. We call it the **backtracking** representation of $P^{(k)}$. Now we can consider these polynomials of round $k+1$ and get the backtracking representation of them. By Lemma 27, we can get a representation of $P^{(k)}$ by composite operators and polynomials in round $k + 2$. Then, we can do the process recursively. In the process of computing the backtracking representation, when meet an input polynomial, we stop representing this polynomial by the ones of higher round. At last, we backtrack to the round n, and eliminate the terms composed of the same

operators and polynomials. Note that the polynomials of round n are all from the input. Then we have

$$P^{(k)} = \sum_{i=1}^{r_n} \sum_{L_j \in T_{n,i}} L_j Q_i^{(n)} + \sum_{i=1}^{r_{n-1}} \sum_{L_j \in T_{n-1,i}} L_j Q_i^{(n-1)} + \cdots + \sum_{i=1}^{r_{k+1}} \sum_{L_j \in T_{k+1,i}} L_j Q_i^{(k+1)} \tag{18}$$

or

$$P^{(k)} = \sum_{i=1}^{r_n} \sum_{L_j \in T_{n,i}} L_j Q_i^{(n)} + \sum_{i=1}^{r_{n-1}} \sum_{L_j \in T_{n-1,i}} L_j Q_i^{(n-1)} + \cdots + \sum_{i=1}^{r_{k+1}} \sum_{L_j \in T_{k+1,i}} L_j Q_i^{(k+1)} + 1 \tag{19}$$

where $T_{m,i} \subseteq \mathcal{S}_{k+1,m}$ is a set of composite operators and $Q_i^{(m)}$ is an input polynomial with class m ($m = k+1, \ldots, n$, $i = 1, \ldots, r_m$). The appearance of 1 is due to the equation (3) of Lemma 27. The number of different polynomials in the above equation, denoted by N, is $r_{k+1} + r_{k+2} + \cdots + r_n$.

Now we will give an upper bound for N. It is easy to see that, when we backtrack to the round $k+1$, there exist at most two different polynomials. Suppose that now we backtrack to the round $k+i$, and there are t different polynomials in the representation. Then, t_1 of them are the form of $\mathcal{R}_{k+i+1} f$, where f is a polynomial with $\mathrm{cls}(f) < k+i+1$; t_2 of them are the form of $\mathcal{J}_{k+i+1} g$, where $\mathrm{cls}(g) = k+i+1$; t_3 of them are input polynomials. Thus, the others can be represented as $\mathcal{R}_{k+i+1} h + \mathcal{R}_{k+i+1} h_i$, where h is a fixed polynomial with $\mathrm{cls}(h) = k+i+1$ and h_i is some polynomial with $\mathrm{cls}(h_i) = k+i+1$. Therefore, the number of different polynomials in the representation of round $k+i+1$ is at most $2(t - t_1 - t_2 - t_3) - (t - t_1 - t_2 - t_3 - 1) + t_1 + t_2 + t_3 = t + 1$. Hence, when we backtrack to the round n, we have $N \le n - k + 1$.

For any $m = k+1, \ldots, n$, $i = 1, \ldots, r_m$, since $T_{m,i} \subseteq \mathcal{S}_{k+1,m}$, by Lemma 28, we have $\sum_{L_j \in T_{m,i}} \|L_j Q_i^{(m)}\| \le \sum_{L_j \in \mathcal{S}_{k+1,m}} \|L_j Q_i^{(m)}\| \le \|Q_i^{(m)}\|$.

(a) Suppose that $P^{(k)}$ is of form (18). We have $\|P^{(k)}\| \le \sum_{m=k+1}^{n} \sum_{i=1}^{r_m} \|Q_i^{(m)}\|$ where $r_{k+1} + \cdots + r_n \le n - k + 1 \le n$.

(b) Suppose the representation of $P^{(k)}$ is Eq. (19). It is easy to see that there exists a term of the form $\mathcal{R}_{k+1} \cdots \mathcal{R}_{k+i-1} \mathcal{J}_{k+i} L Q^{(k+j)}$, where $Q^{(k+j)}$ is an input polynomial with class $k+j$, $L \in \mathcal{S}_{k+i+1,k+j}$ and $\mathrm{cls}(LQ^{(k+j)}) = k+i$. If $\mathrm{init}(LQ^{(k+j)}) = W + 1$ where W is a polynomial without a constant term, we have $\mathcal{J}_{k+i} LQ^{(k+j)} = W$. Therefore $\|\mathcal{J}_{k+i} LQ^{(k+j)}\| + \|\mathcal{R}_{k+i} LQ^{(k+j)}\| < \|LQ^{(k+j)}\|$. Hence, $\|P^{(k)}\| < \sum_{m=k+1}^{n} \sum_{i=1}^{r_m} \|Q_i^{(m)}\| + 1$ which means $\|P^{(k)}\| \le \sum_{m=k+1}^{n} \sum_{i=1}^{r_m} \|Q_i^{(m)}\|$. If $\mathrm{init}(LQ^{(k+j)}) = W$ where W is a polynomial without a constant term, we have $\mathcal{J}_{k+i} LQ^{(k+j)} = W + 1$. Thus, $P^{(k)} = \mathcal{R}_{k+1} \cdots \mathcal{R}_{k+i-1} \mathcal{J}_{k+i} LQ^{(k+j)} + 1 + E = \mathcal{R}_{k+1} \cdots \mathcal{R}_{k+i-1} W + E$ where E is the sum of other terms in Eq. (19). Obviously, $\|\mathcal{R}_{k+1} \cdots \mathcal{R}_{k+i-1} W\| < \|\mathcal{R}_{k+1} \cdots \mathcal{R}_{k+i-1}(W+1)\| = \|\mathcal{R}_{k+1} \cdots \mathcal{R}_{k+i-1} \mathcal{J}_{k+i} LQ^{(k+j)}\|$. Then we have $\|P\| < \|\mathcal{R}_{k+1} \cdots \mathcal{R}_{k+i-1} \mathcal{J}_{k+i} LQ^{(k+j)}\| + \|E\| \le \sum_{m=k+1}^{n} \sum_{i=1}^{r_m} \|Q_i^{(m)}\|$.

In summary, we always have $\|P^{(k)}\| \le \sum_{m=k+1}^{n} \sum_{i=1}^{r_m} \|Q_i^{(m)}\|$ where $r_{k+1} + \cdots + r_n \le n - k + 1 \le n$. □

The following result shows that even the size of the monomials occurring in the algorithms is nicely bounded.

Corollary 29. *Let M be the set of distinct monomials which are contained in some polynomial occurring in Algorithm* **MFTriSet** *and $H = \sum_{m \in M} \|m\|$. Then, we have $H \le \sum_{P \in \mathbb{P}} \mathrm{cls}(P) \|P\| + 1$ where $\mathbb{P}$ is the input of the algorithm.*

Proof. From the proof of Theorem 26, a polynomial P occurring in the Algorithm **MFTriSet** must have form (18) or (19). Then, a monomials m of P must be either 1 or contained in some $LQ^{(k)}$, where $Q^{(k)}$ is an input polynomial with class k and $L \in \mathcal{S}_{k-i,k}$. Thus, H is not bigger than the sum of the length of all such LQ and 1. From Lemma 28, $\sum_{L_{i_2} \in \mathcal{S}_{2,k}} \|L_{i_2} Q^{(k)}\| + \cdots + \sum_{L_{i_k} \in \mathcal{S}_{k,k}} \|L_{i_k} Q^{(k)}\| + \|Q^{(k)}\| \le k \|Q^{(k)}\|$. Considering all input polynomials P and 1, we get the corollary. □

5.3. Complexity analysis of **MFTriSet**

For a polynomial set $\mathbb{P}$, we define $\mathrm{tdeg}(\mathbb{P})$ to be the highest total degree of the elements in $\mathbb{P}$. In this section, we will always consider a Boolean polynomial set $\mathbb{P}$ with l polynomials and $\mathrm{tdeg}(\mathbb{P}) = d$.

Theorem 30. *For an input polynomial set $\mathbb{P}$ with $|\mathbb{P}| = l$ and $\mathrm{tdeg}(\mathbb{P}) = d$, the bitsize complexity of* **MFTriSet** *is $O(ln^{d+1}\sum_{P\in\mathbb{P}}\mathrm{term}(P))$. If $l \geq n$, the bitsize complexity of* **MFTriSet** *is $O(ln^{d+2}M)$ where $M = \max_{P\in\mathbb{P}}\mathrm{term}(P)$.*

As a consequence, Algorithm **MFTriSet** is a polynomial-time algorithm for a small d. For all the examples in Section 6, we have $d \leq 4$ and n ranges from 40 to 128. For such examples, the complexity is $O(n^8M)$ since l is roughly $O(n^2)$.

We will prove Theorem 30 in the rest of this section. As in Section 5.2, we assume that in the k-th round of **MFTriSet** started as step 2, we deal with the polynomials of class k, which is the worst case. Suppose that we have l_k polynomials with class k in the k-th round. Since the complexity of computing $I + 1$ is smaller than that of doing the polynomial additions, we only consider the addition of two polynomials. Then we need to do $l_k - 1$ polynomial additions in order to eliminate x_k. Thus, if we can estimate the number of the polynomials in $\mathbb{P}$ in every round, then we can obtain the complexity bound of **MFTriSet**. Note that, in Step 2.5 of **MFTriSet**, we choose a Q with the lowest degree, which is important for the complexity analysis.

Suppose that we have a polynomial set $\mathbb{S} = \{P_1, \ldots, P_l\}$ with class n, which is the worst case. After eliminating x_n, we obtain two sets of polynomials:

$$\mathbb{S}_J = \{\mathcal{J}_n P | P \in \mathbb{S}\}, \qquad \mathbb{S}_R = \{\mathcal{R}_n(P_s + P) | P \in \mathbb{S}\}$$

where P_s is a fixed polynomial with lowest degree in $\mathbb{S}$ and $\{\mathcal{J}_n, \mathcal{R}_n\}$ are the operators defined in (17). Note that $\mathrm{tdeg}(\mathbb{S}_J) \leq d - 1$ and $\mathrm{tdeg}(\mathbb{S}_R) \leq d$. Moreover, $|\mathbb{S}_J| \leq l$ and $|\mathbb{S}_R| \leq l$. After eliminating x_{n-1}, we have four polynomial sets:

$$\mathbb{S}_{JJ} = \{\mathcal{J}_{n-1} P | P \in \mathbb{S}_J\}, \qquad \mathbb{S}_{JR} = \{\mathcal{J}_{n-1} P | P \in \mathbb{S}_R\},$$
$$\mathbb{S}_{RJ} = \{\mathcal{R}_{n-1}(P_s + P) | P \in \mathbb{S}_J\}, \qquad \mathbb{S}_{RR} = \{\mathcal{R}_{n-1}(P_s + P) | P \in \mathbb{S}_R\}.$$

Similarly, $|\mathbb{S}_{JJ}|, |\mathbb{S}_{RJ}| \leq |\mathbb{S}_J| \leq l$ and $|\mathbb{S}_{JR}|, |\mathbb{S}_{RR}| \leq |\mathbb{S}_R| \leq l$. Since P_s is a polynomial with the lowest degree, we have $\mathrm{tdeg}(\mathcal{R}_{n-1}(P_s + P)) \leq \mathrm{tdeg}(P)$ which means that $\mathrm{tdeg}(\mathbb{S}_{RR}) \leq \mathrm{tdeg}(\mathbb{S}_R)$ and $\mathrm{tdeg}(\mathbb{S}_{RJ}) \leq \mathrm{tdeg}(\mathbb{S}_J)$. For the other two sets, we can conclude $\mathrm{tdeg}(\mathbb{S}_{JJ}) \leq \mathrm{tdeg}(\mathbb{S}_J) - 1 \leq d - 2$ and $\mathrm{tdeg}(\mathbb{S}_{JR}) \leq \mathrm{tdeg}(\mathbb{S}_R) - 1 \leq d - 1$.

Recursively, we have the following sequence

$$(\mathbb{S}) \to (\mathbb{S}_J, \mathbb{S}_R) \to (\mathbb{S}_{JJ}, \mathbb{S}_{JR}, \mathbb{S}_{RR}, \mathbb{S}_{RJ}) \to \cdots. \tag{20}$$

For a set $\mathbb{S}_{O_1O_2\cdots O_k}$ where O_i is J or R, we have $|\mathbb{S}_{O_1O_2\cdots O_k}| \leq l$. We can deduce that $\mathrm{tdeg}(\mathbb{S}_{O_1O_2\cdots O_k}) \leq d - s$ where s is the number of O_i which is J. Therefore, the number of J occurring in the subscript of $\mathbb{S}$ can be $d - 1$ at most. As a consequence, in round $n - k$ corresponding to the $(k + 1)$-th part of the sequence (20), the number of $\mathbb{S}_i$ is at most $\binom{k}{0} + \binom{k}{1} + \cdots + \binom{k}{d-1}$. Thus, the number of polynomials in round $n-k$ is at most $l(\sum_{i=0}^{d-1}\binom{k}{i})$. It implies that we need at most $l(\sum_{k=0}^{n-1}\sum_{i=0}^{d-1}\binom{k}{i}) = l(\sum_{i=1}^{d}\binom{n}{i})$ polynomial additions in the algorithm. It is easy to prove that in other simpler cases, the times of additions are still bounded by $l(\sum_{i=1}^{d}\binom{n}{i})$ or $O(ln^d)$.

Now let us estimate the complexity of polynomial additions in **MFTriSet**. We can define an operator $\mathcal{I}_k$ as follows: if $\mathrm{cls}(P) = k$, $\mathcal{I}_k(P) = \mathrm{init}(P)$; if $\mathrm{cls}(P) < k$, $\mathcal{I}_k(P) = 0$. It is easy to prove that if we substitute $\mathcal{J}_i$ with $\mathcal{I}_i$ in Eqs. (18) and (19) of Section 5.2, any of the two equations will either be unchanged or become itself plus one. Now we use $\mathrm{term}(P)$ to denote the number of monomials occurring in P. Then we have $\mathrm{term}(\mathcal{I}P) + \mathrm{term}(\mathcal{R}P) \leq \mathrm{term}(P)$. Similar to the proof of Theorem 26, we can prove the following lemma

Lemma 31. *Let n be the number of variables and $\mathbb{P}$ the input of Algorithm* **MFTriSet**. *Then, for any polynomial T occurring in* **MFTriSet**, *we have $\mathrm{term}(T) \leq \sum_{P\in\mathbb{P}}\mathrm{term}(P) + 1$. If $|\mathbb{P}| > n$, then there exist n polynomials $P_1, \ldots, P_n$ in $\mathbb{P}$ such that $\mathrm{term}(T) \leq \mathrm{term}(P_1) + \mathrm{term}(P_2) + \cdots + \mathrm{term}(P_n) + 1$.*

Note that the bitsize complexity of computing the sum of P_1 and P_2 is $O(n(\mathrm{term}(P_1) + \mathrm{term}(P_2)))$. Then the complexity of Algorithm **MFTriSet** is $O(ln^{d+1}(\sum_{P\in\mathbb{P}}\mathrm{term}(P)))$. We have proved Theorem 30.

6. Experimental results

We have implemented algorithms **TDCS** and **MFCS** in $\mathbb{R}_2$ with the C language and tested them with a large number of polynomial systems. In order to save storage space, we use the SZDD to store the polynomials in our implementation (Minto, 1993).

For comparison, we also use the Gröbner basis algorithm (F4) in Magma with Degree Reverse Lexicographic order, denoted by **GB**, to solve these polynomial systems. The experiments are done on a PC with a 3.19 GHz CPU, 2 G memory, and a Linux OS. The running times in the tables are all given in seconds.

6.1. Boolean matrix multiplication problem

For two $n \times n$ Boolean matrices A and B, if $AB = I$, by the linear algebra we can deduce that $BA = I$, where I is the $n \times n$ identity matrix. However, if we want to check the conclusion by reasoning, it will become an extremely difficult problem. This challenge problem was proposed by Stephen Cook in his invited talk at SAT 2004 (Cook, 2004; Cook and Nguyen, 2010). The best known result was that the problem of $n = 5$ can be solved by SAT-solvers in about 800–2000 s. The problem of $n = 6$ were still unsolved (Biere, 2008).

Now we test our software for this problem by converting the problem into the solving of a Boolean polynomial system. By setting the entries of A and B to be $2n^2$ distinct variables, we can obtain n^2 quadratic polynomials from $AB = I$. Then we compute the Gröbner basis or the zero decomposition of this polynomials, and check whether the polynomials generated by $BA = I$ can be reduced to 0 by the Gröbner basis or by every characteristic set in the zero decomposition. In this way, we can prove the conclusion.

We use the CS method to illustrate the above procedure. Let $\mathbb{P}_1$ and $\mathbb{P}_2$ be the polynomial sets generated by $AB = I$ and $BA = I$ respectively. With the CS method, we have

$$\mathrm{Zero}_q(\mathbb{P}_1) = \cup_i \mathrm{Zero}_q(\mathscr{A}_i)$$

where $\mathscr{A}_i$ are triangular sets. If $\mathrm{prem}(P, \mathscr{A}_i) = 0$ for all possible i and $P \in \mathbb{P}_2$, then we have solved the problem. It is clear that the major difficulty here is to compute the decomposition.

For $n = 4, 5, 6$, the numbers of variables are $32, 50, 72$ respectively. Therefore, computing the Gröbner basis or the zero decomposition of this polynomials will be a hard work. We used **GB** and our **MFCS** algorithm to solve the problem with $n = 4, 5, 6$. The running time given in Table 1 includes solving the equations generated by $AB = I$ and checking the conclusion $BA = I$. Notation • means memory overflow.

6.2. Equations from stream ciphers based on nonlinear filter generators

In this section we generate our equations from stream ciphers based on LFSRs. We first show how these polynomial systems are generated. A linear feedback shift register (LFSR) of length L can be simply considered as a sequence of L numbers $(c_1, c_2, \ldots, c_L)$ from $\mathbb{F}_2$ such that $c_L \neq 0$ (Menezes et al., 1996). For an **initial state** $S_0 = (s_0, s_1, \ldots, s_{L-1}) \in \mathbb{F}_2^L$, we can use the given LFSR to produce an infinite sequence satisfying

$$s_i = c_1 s_{i-1} + c_2 s_{i-2} + \cdots + c_L s_{i-L}, \quad i = L, L+1, \ldots. \tag{21}$$

A key property of an LFSR is that if the related **feedback polynomial** $P(x) = c_L x^L + c_{L-1}x^{L-1} + \cdots + c_1 x - 1$ is primitive, then the sequence (21) has period $2^L - 1$ (Menezes et al., 1996). The number of nonzero coefficients in P is called the **weight** of P, denoted by w_P.

An often used technique in stream ciphers to enhance the security of an LFSR is to add a **nonlinear filter** to the LFSR. Let $f(x_1, \ldots, x_m)$ be a Boolean polynomial with m variables. We assume that $m \leq L$. Then we can use f and the sequence (21) to generate a new sequence as follows

$$z_t = f(s_{t+k_1}, s_{t+k_2} \ldots, s_{t+k_m}), \quad t = 0, 1, \ldots \tag{22}$$

where $\{k_i\}_{1\leq i\leq m}$ is called the **tapping sequence**. A combination of an LFSR and a nonlinear polynomial f is called a **nonlinear filter generator** (NFG).

The filter functions used in this paper are due to Canteaut and Filiol (2001):

- Canfil 1, $x_1x_2x_3 + x_1x_4 + x_2x_5 + x_3$
- Canfil 2, $x_1x_2x_3 + x_1x_2x_4 + x_1x_2x_5 + x_1x_4 + x_2x_5 + x_3 + x_4 + x_5$

- Canfil 8, $x_1x_2x_3 + x_2x_3x_6 + x_1x_2 + x_3x_4 + x_5x_6 + x_4 + x_5$
- Canfil 9, $x_2x_4x_5x_7 + x_2x_5x_6x_7 + x_3x_4x_6x_7 + x_1x_2x_4x_7 + x_1x_3x_4x_7 + x_1x_3x_6x_7 + x_1x_4x_5x_7 + x_1x_2x_5x_7 + x_1x_2x_6x_7 + x_1x_4x_6x_7 + x_3x_4x_5x_7 + x_2x_4x_6x_7 + x_3x_5x_6x_7 + x_1x_3x_5x_7 + x_1x_2x_3x_7 + x_3x_4x_5 + x_3x_4x_7 + x_3x_6x_7 + x_5x_6x_7 + x_2x_6x_7 + x_1x_4x_6 + x_1x_5x_7 + x_2x_4x_5 + x_2x_3x_7 + x_1x_2x_7 + x_1x_4x_5 + x_6x_7 + x_4x_6 + x_4x_7 + x_5x_7 + x_2x_5 + x_3x_4 + x_3x_5 + x_1x_4 + x_2x_7 + x_6 + x_5 + x_2 + x_1$
- Canfil 10, $x_1x_2x_3 + x_2x_3x_4 + x_2x_3x_5 + x_6x_7 + x_3 + x_2 + x_1$.

In the experiments, we use our algorithms to find $S_0 = (s_0, s_1, \ldots, s_{L-1})$ by solving the following equations for given c_i, z_i, and f

$$z_t = f(s_{t+k_1}, s_{t+k_2} \ldots, s_{t+k_m}), \quad t = 0, 1, \ldots, k \tag{23}$$

where k is a positive integer, s_i satisfy (21), and $\{k_1, \ldots, k_m\}$ is a tapping sequence.

We compare four different algorithms for solving these equations. Two of them are the **MFCS** and **GB**. Faugère and Perret suggested to us that an incremental version of the Gröbner basis algorithm is faster than **GB** for the equations generated by the LFSR. Therefore, we also compare the incremental Gröbner basis algorithm and the incremental **TDCS**, denoted **IGB** and **ITDCS** respectively. Note that the F5 method (Faugère, 2002) and the CS method presented in (Maza, 2000) also use the incremental technique.

Let HS be the field polynomials $\{x_1^2 + x_1, \ldots, x_n^2 + x_n\}$ and $PS = \{P_1, P_2, \ldots, P_k\}$ be the input polynomials with P_i be the polynomial generated from the i-th output bit. Then we compute the **IGB** by the following codes in Magma:

R⟨x1, . . . ,xn⟩ :=PolynomialRing(GF(2),n,"grevlex");
HS:=[R.i^2+R.i: i in [1..Rank(R)]]; G:=HS;
for i:=1 to k do
G:=G cat [PS.i]; G:= GroebnerBasis(G);
end for;
G.

We did three sets of experiments with increasing difficulties. The test problems are similar to those in (Chai et al., 2008) but are more difficult. We also compare our method with one of the benchmark implementations of the Gröbner basis method on the same computer, which are not given in (Chai et al., 2008).

In the first set of experiments, we choose a simple tapping sequence {0, 1, 2, 3, 4, 5, 6} and the feedback polynomials for $L = 40, 60, 81, 100, 128$ are respectively $x^{40}+x^{21}+x^{19}+x^2+1$, $x^{60}+x^1+1$, $x^{81} + x^4 + 1$, $x^{100} + x^{37} + 1$, $x^{128} + x^{29} + x^{27} + x^2 + 1$. The results are given in Table 2, where L is the number of variables, k is the number of equations (see (23)). k is the smallest number such that the

Canfil8	855.04	*	• after 60 m

In the second set of experiments, we generate more difficult equations in the cases of $L = 40$ and $k = 60$ by changing the feedback polynomial to $x^{40}+x^{35}+x^{32}+x^{27}+x^{24}+x^{19}+x^{15}+x^{12}+x^{7}+x^{1}+1$. The results are given in Table 3.

In the third set of experiments, we generate more dense polynomial systems by changing the tapping sequence. The results are given in Table 4, in which $L = 40$, $k = 55$, the feedback polynomial is $x^{40} + x^{37} + x^{34} + x^{21} + x^{11} + x^{5} + 1$ and the tapping sequence is $\{0, 6, 11, 18, 25, 31, 37\}$. And $*$ means that we have computed over 2 h and did not obtain the solutions.

From the experiments, we have the following observations.

- From Table 2, we can see that for these "simple" examples, **ITDCS** is the fastest method. **IGB** and **MFCS** are also very efficient with **MFCS** better than **IGB** in most cases. **GB** tends to generate large polynomials and causes memory overflow.
- From Table 3, we can see that for these "moderately difficult" polynomial systems, **ITDCS** is still the fastest method. Now, **IGB** performs better than **MFCS**.
- From Table 4, we can see that for the "most difficult" polynomial systems, **MFCS** is the only algorithm that can find the solutions on our computer. **IGB** and **GB** quickly use all the memory and cause memory overflow. **ITDCS** has been run for two hours without giving a result. The reason is that, in this case, **ITDCS** and **IGB** need to deal with some high degree and dense polynomials. On the other hand, due to Theorems 26 and 30, the polynomials occurring in Algorithm **MFCS** are much smaller.

In summary, Algorithm **MFCS** seems to be the most efficient and stable approach to deal with these kinds of polynomial systems. The main reason is that the size of the polynomials in this algorithm is effectively controlled due to Theorems 26 and 30. To use SZDD (Minto, 1993) to represent polynomials is another key factor in memory saving. Note that SZDD suits the CS method very well. The CS method will generate a large number of components and the polynomial sets representing different components differ only for a very few number of polynomials due to the way of generating new

Table 5
The number of components for the examples in Table 4.

	Canfil1	Canfil2	Canfil3	Canfil4	Canfil5	Canfil6	Canfil7	Canfil8
N_C	13749	23881	7251	1657	1086	3331	1551	180710
$R \approx$	2^{-26}	2^{-25}	2^{-27}	2^{-29}	2^{-30}	2^{-28}	2^{-29}	2^{-24}

components (see Step 2.6.3 of Algorithm 1). Then different polynomial sets will share memory for their common polynomials, and as a consequence, the total memory consumption is well contained.

For Algorithm **MFCS**, the bottle neck problem is how to control the number of components (that is, the number of polynomial sets in $\mathbb{P}^*$ in the output of Algorithm **MFTriSet**). Theoretically, this number is exponential in the worst case. Practically, this number could also be very large. But, comparing to the number 2^L of exhaust search, the number of components generated in **MFTriSet** is still very small. In Table 5, we give the numbers of components for each example in Table 4. In this table, N_C is the number of components and $R = \frac{N_C}{2^L}$ could be considered as a measure of effectiveness of Algorithm **MFTriSet**. We can see that R is very small for all examples.

6.3. Attack on Bivium-A

Bivium is a simple version of the eSTREAM (2005) stream cipher candidate Trivium. It is built on the same design principles of Trivium. The intention is to reduce the complexity of Trivum, and to extend the attacks on Bivium to Trivium. Bivium has two versions Bivium-A and Bivium-B. Here we focus on attacking Bivium-A. There have been several successful attacks on Bivium-A, and we want to show that our algorithm is comparable with these algorithms.

The Bivium-A is given by the following pseudo-code:

$$
\begin{aligned}
&\text{for } i = 1 \text{ to } N \text{ do}\\
t_1 &\leftarrow s_{66} + s_{93}\\
t_2 &\leftarrow s_{162} + s_{177}\\
z_i &\leftarrow t_2\\
t_1 &\leftarrow t_1 + s_{91} \cdot s_{92} + s_{171}\\
t_2 &\leftarrow t_2 + s_{175} \cdot s_{176} + s_{69}\\
(s_1, s_2, \ldots, s_{93}) &\leftarrow (t_2, s_1, \ldots, s_{92})\\
(s_{94}, s_{95}, \ldots, s_{177}) &\leftarrow (t_1, s_{94}, \ldots, s_{176}).
\end{aligned}
$$

We want to recover the initial state $(s_1, \ldots, s_{177})$ from the given N output bits $(z_1, \ldots, z_N)$. Note that the degree of the equations will increase after several clocks. In order to avoid this problem, we can introduce two new variables and two equations for each clock:

$$s_{178} = s_{66} + s_{93} + s_{91} \cdot s_{92} + s_{171} \tag{24}$$

$$s_{179} = s_{162} + s_{177} + s_{175} \cdot s_{176} + s_{69}. \tag{25}$$

Then we can obtain a Boolean polynomial system with $2N + 177$ variables and $3N$ equations.

The results of the successful attacks on Bivium-A (Mcdonald et al., 2007; Raddum, 2006; Simonetti et al., 2008)[1] is given in Table 6.

In our experiments, we use the algorithm **MFCS** and the equations are generated by adding two new variables for each clock. We run **MFCS** on a sample of 100 different random initial states. We observed that the different initial keys make a great difference to the results. For every initial state, we can find a number M. When the number of output bits N is not less than M, the equations can be solved within one minute. When N becomes much bigger, the running time will increase slowly. However, if N is less than M, the running time will be much longer than one minute. From our experiment results, the value of M is from 200 to 700. In our experiments, we set $N = 700$.

[1] In (Simonetti et al., 2008), they give four different results by solving in different ways. Here we only list the result by adding new variables but without guessing any variables.

Table 6
The known results for Bivium-A.

Method	Graph for sparse system	SatSolver	Gröbner Basis
Time	"about a day"	21 sec	400 sec
Output Bits	177	177	2000

The average time for solving the problem by **MFCS** with 700 output bits is 49.3 s. We also tried to use **GB** to solve the same sample by the same computer. The equations are also generated by adding two variables for each clock. In order to solve the equations, we need 1700 output bits. If the output is less than 1700 bits, the memory will be exhausted. For $N = 1700$, the average time for solving the problem by **GB** is 303.3 s. If we set $N = 2000$ as in (Simonetti et al., 2008), the average time is 521.6 seconds. From the results, we can see that our algorithm is comparable with the known successful algorithms in this problem.

7. Conclusions

In this paper, we present two algorithms **TDCS** and **MFCS** to solve nonlinear equation systems in finite fields based on the idea of characteristic set. Due to the special property of finite fields, the given algorithms have better properties than the general characteristic set method. In particular, we obtain an explicit formula for the number of solutions of an equation system, and give the bitsize complexity of Algorithm **TDCS** for Boolean polynomials. We also prove that the size of the polynomials in **MFCS** can be effectively controlled, which allows us to avoid the expression swell problem effectively.

We test our methods by solving polynomial systems generated by the Boolean matrix problem, stream cipher Bivium-A and stream ciphers based on nonlinear filter generators. All these equations have block triangular structure. Extensive experiments show that our methods are efficient for solving this kind of equations and Algorithm **MFCS** seems to be the most efficient and stable approach for these problems.

The experiments are only done for Boolean polynomials in this paper. It our future work to see whether the algorithms proposed in this paper can be developed into practically efficient software packages for finite fields other than $\mathbb{F}_2$. It is expected that elimination techniques developed in previous work on CS methods will also be needed.
